

# Development of a New type of Sandwich calorimeter with lead-glass and glass-scintillator

Tohru Takeshita (Shinshu)  
@CALOR2024

- Homogeneous calorimeter simulation

T. Takeshita *et al* 2020 *JINST* 15 C05015

DSC

- Double Readout **GLASS** Sandwich Cal.

radiation tolerance and cost effective

T.Takeshita & R. Terada, arXiv 2306.16325

# Particles in the Higgs Factory

calorimeter

particles ( $e/\gamma$ ,  $\pi/K$ ), mostly  $E < 20\text{GeV}$

- Ejet  $\sim 5-100$  GeV
- PFA Jet Energy resolution is worse
- due to intrinsic Energy resolution of the calorimeter
- How to solve the problem >>>

# Particles in the Higgs Factory

calorimeter

particles ( $e/\gamma$ ,  $\pi/K$ ), mostly  $E < 20\text{GeV}$

- **Ejet ~5-100 GeV**
- PFA Jet Energy resolution is worse
- due to **intrinsic Energy resolution** of the calorimeter
- How to solve the problem >>>

start from

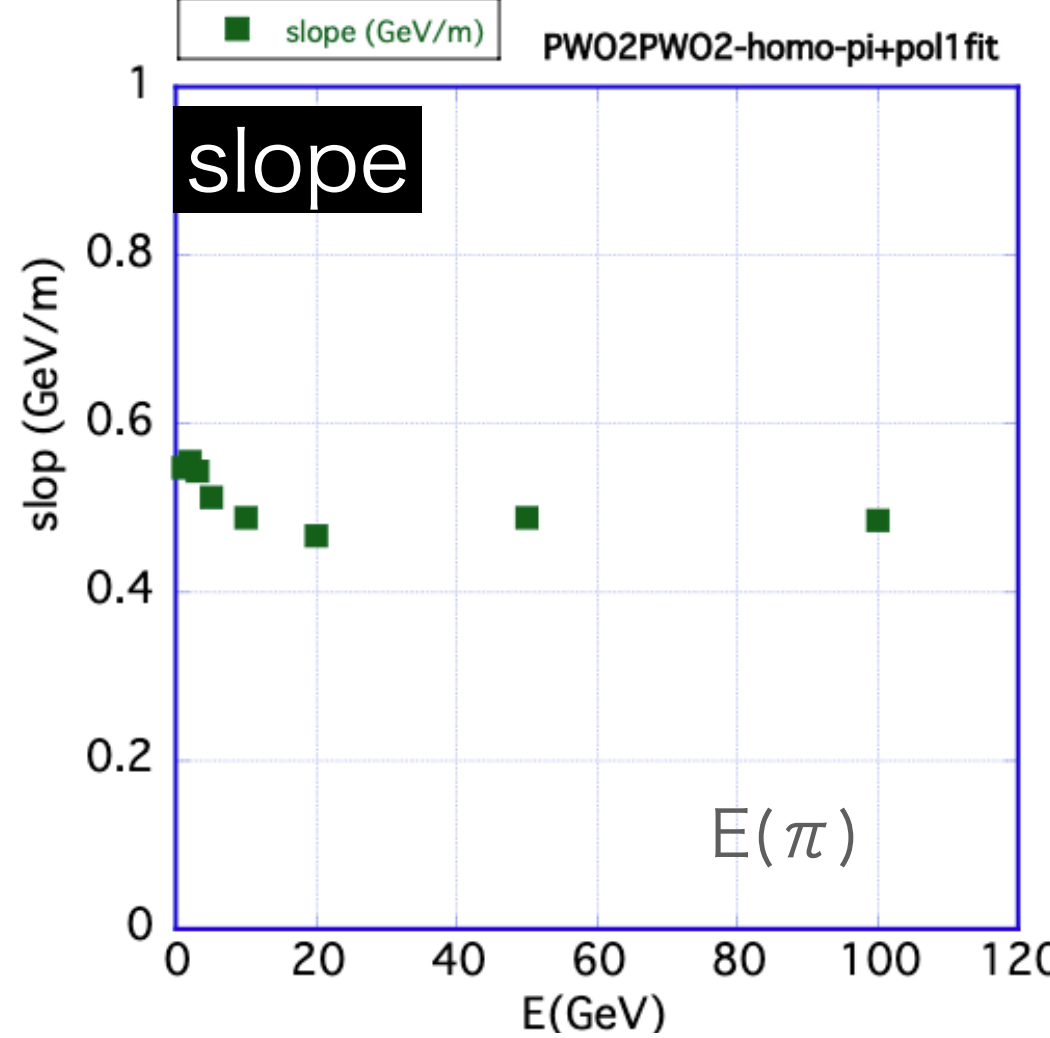

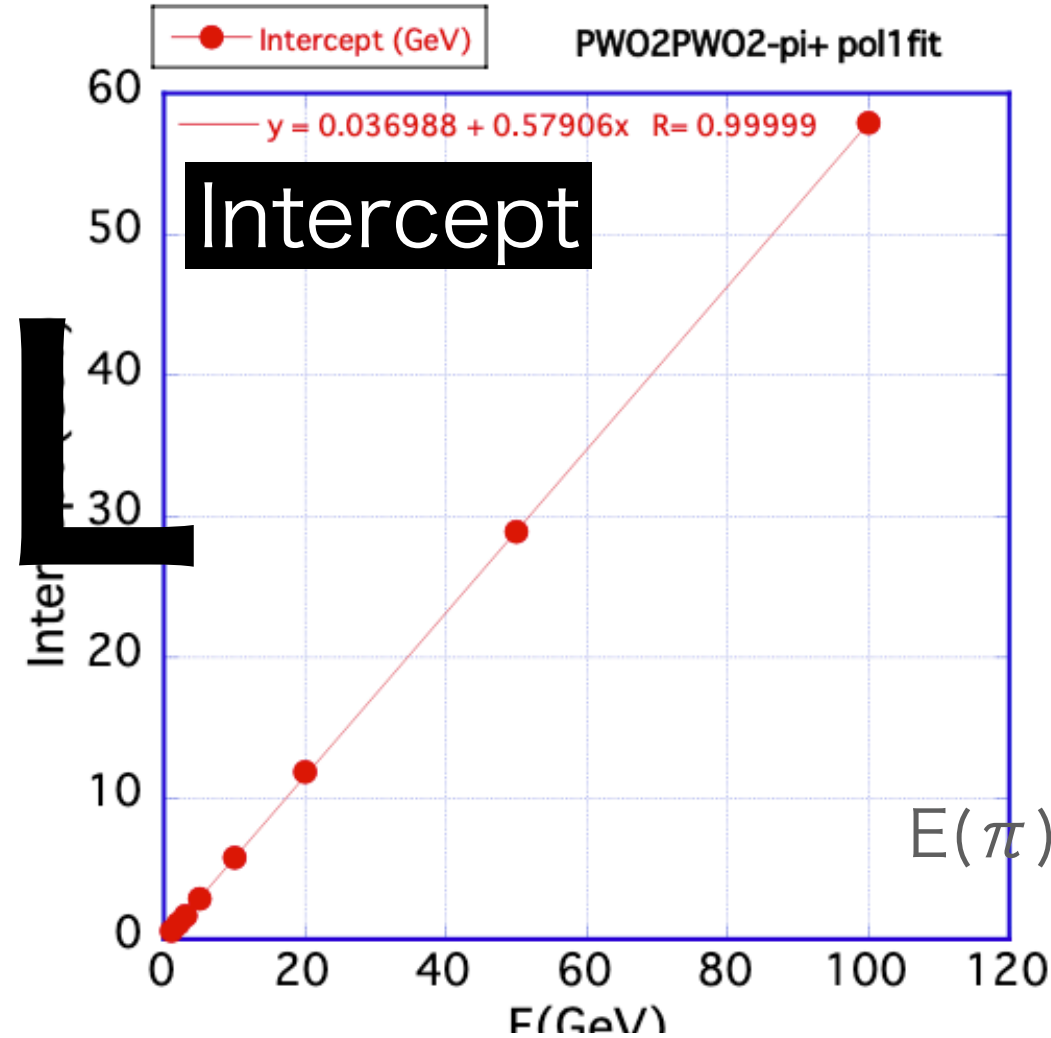

# Homogeneous CAL

simulation

two parameters are suitable to be measured

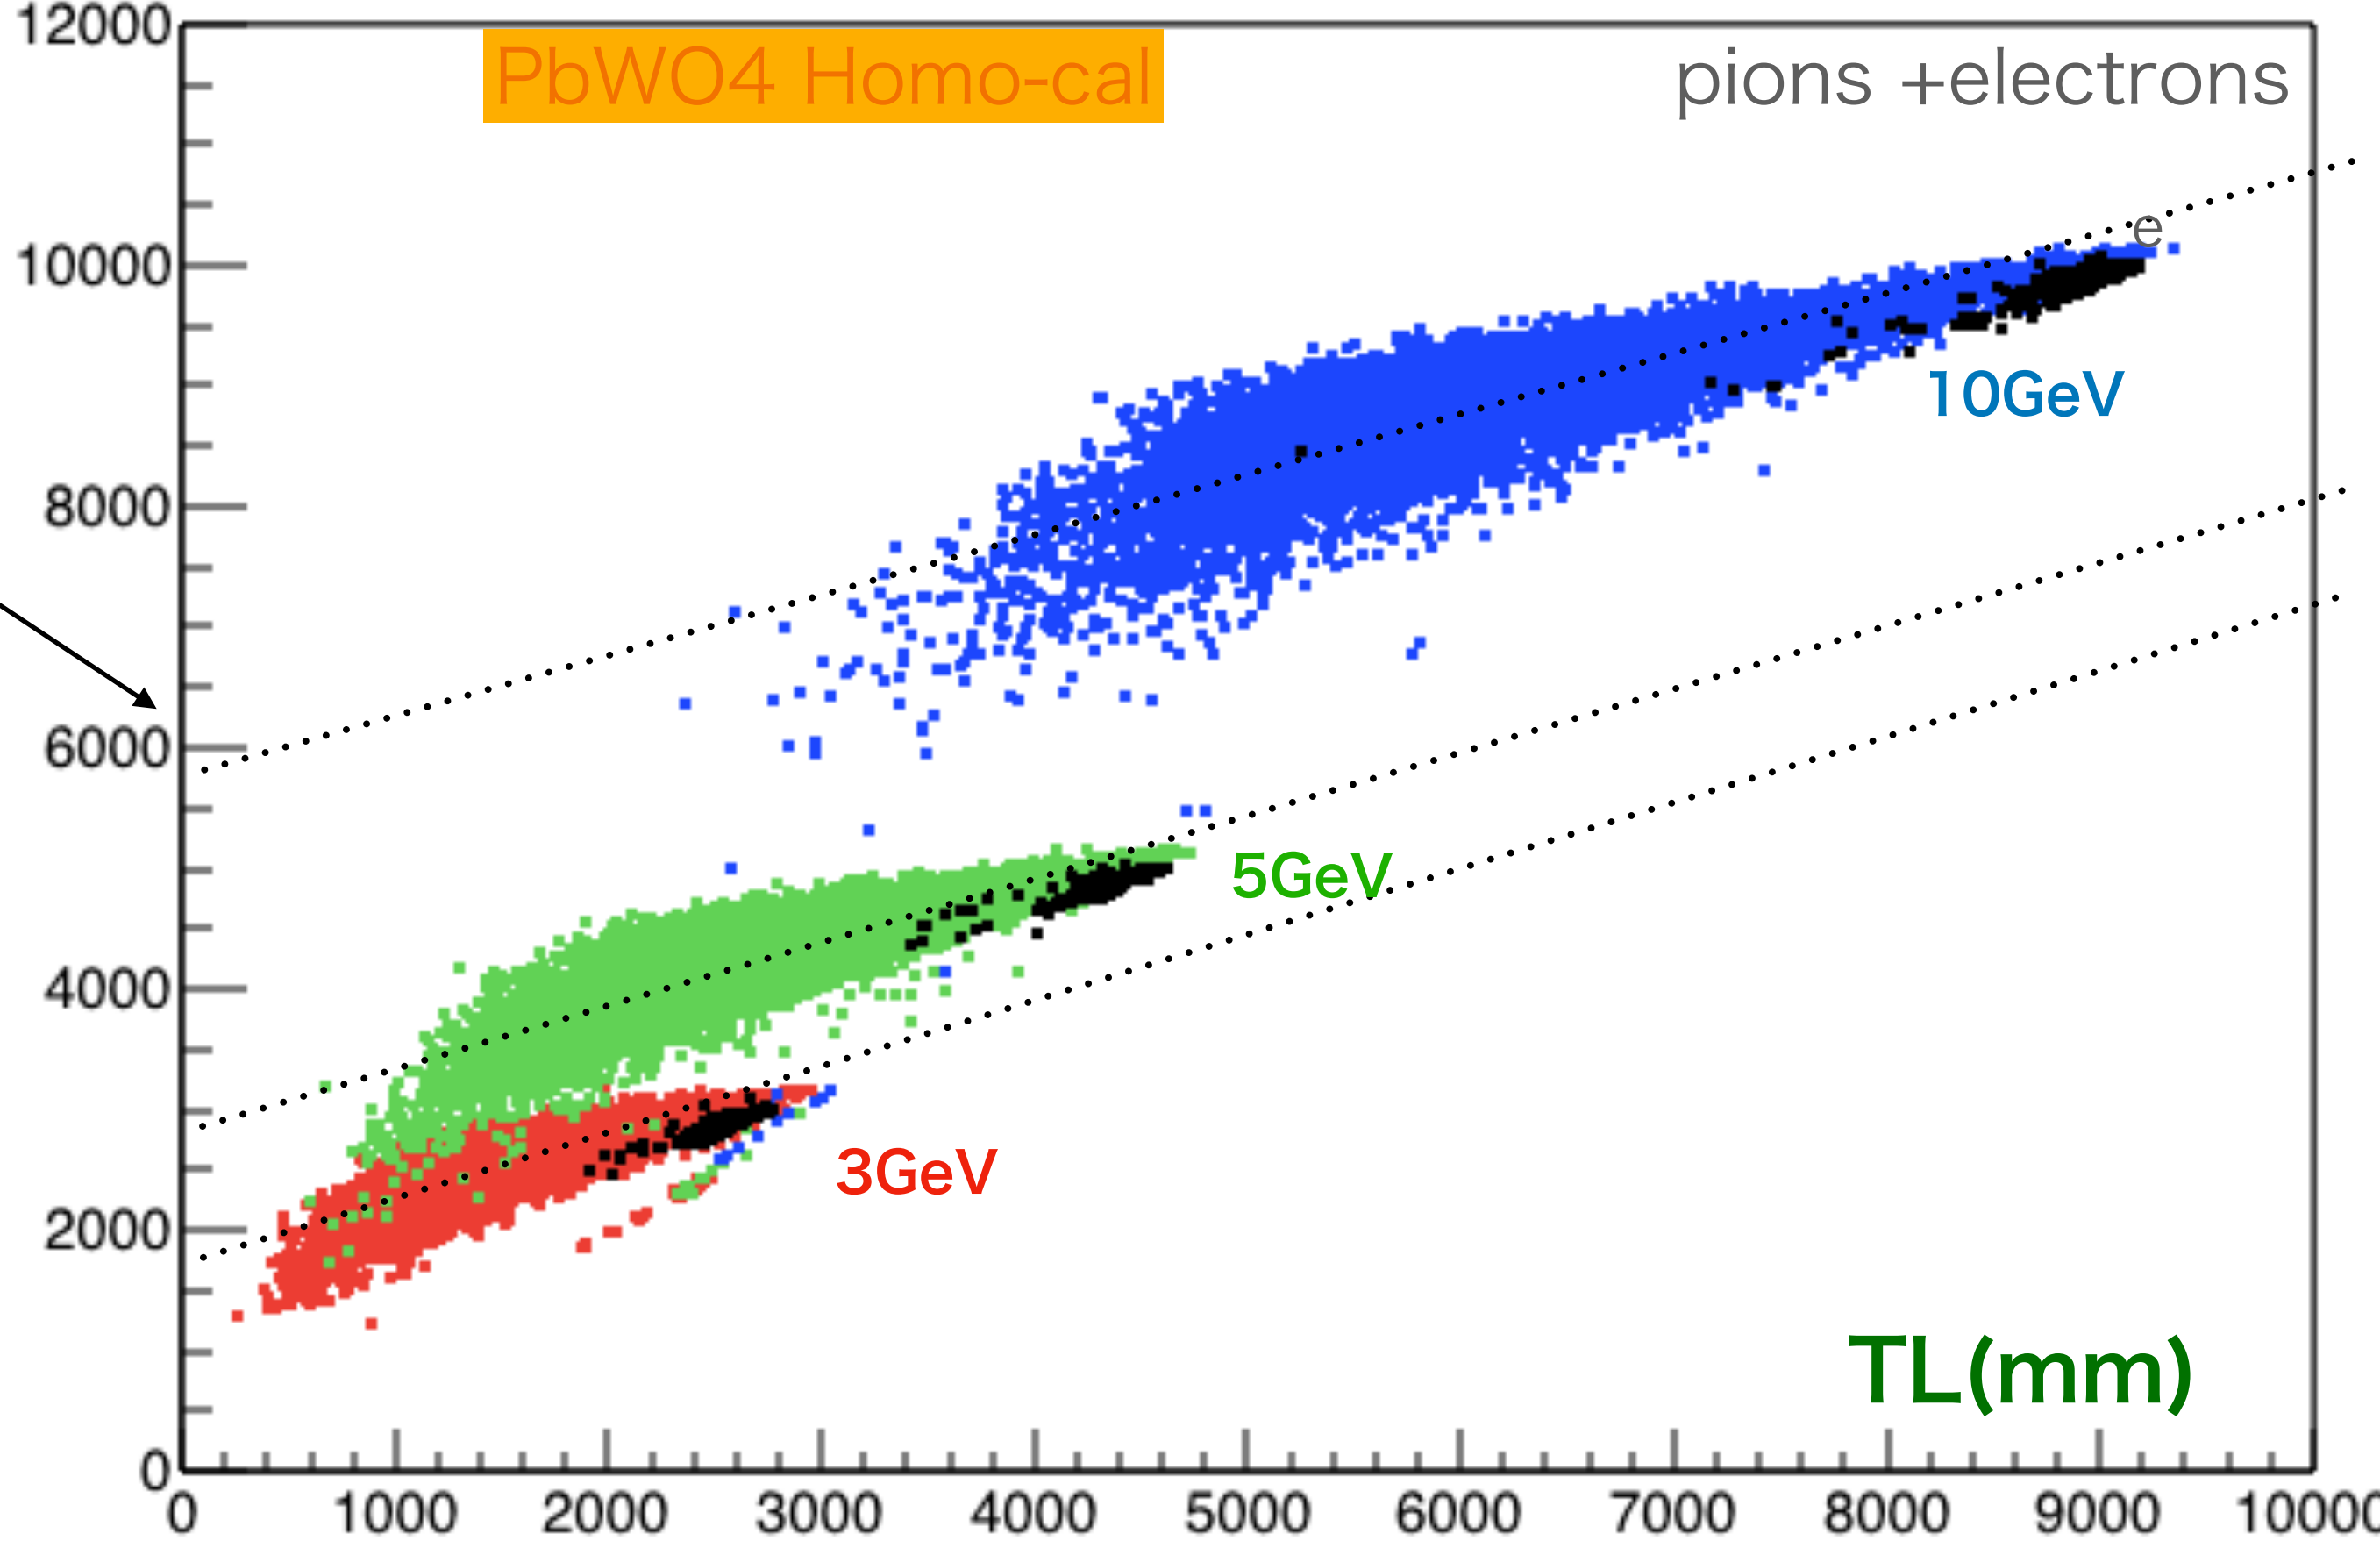

- sum of Track Length (TL) ~ Cherenkov lights
- sum of Energy Deposit (ED) ~ Scintillation light
- strong correlation between ED and TL

ED(MeV)

## Relations

- strong correlation : simple linear behavior without passing the origin
  - intercept → linearity
  - slope → constant independent of energy
- common for e/pi/K/p/n

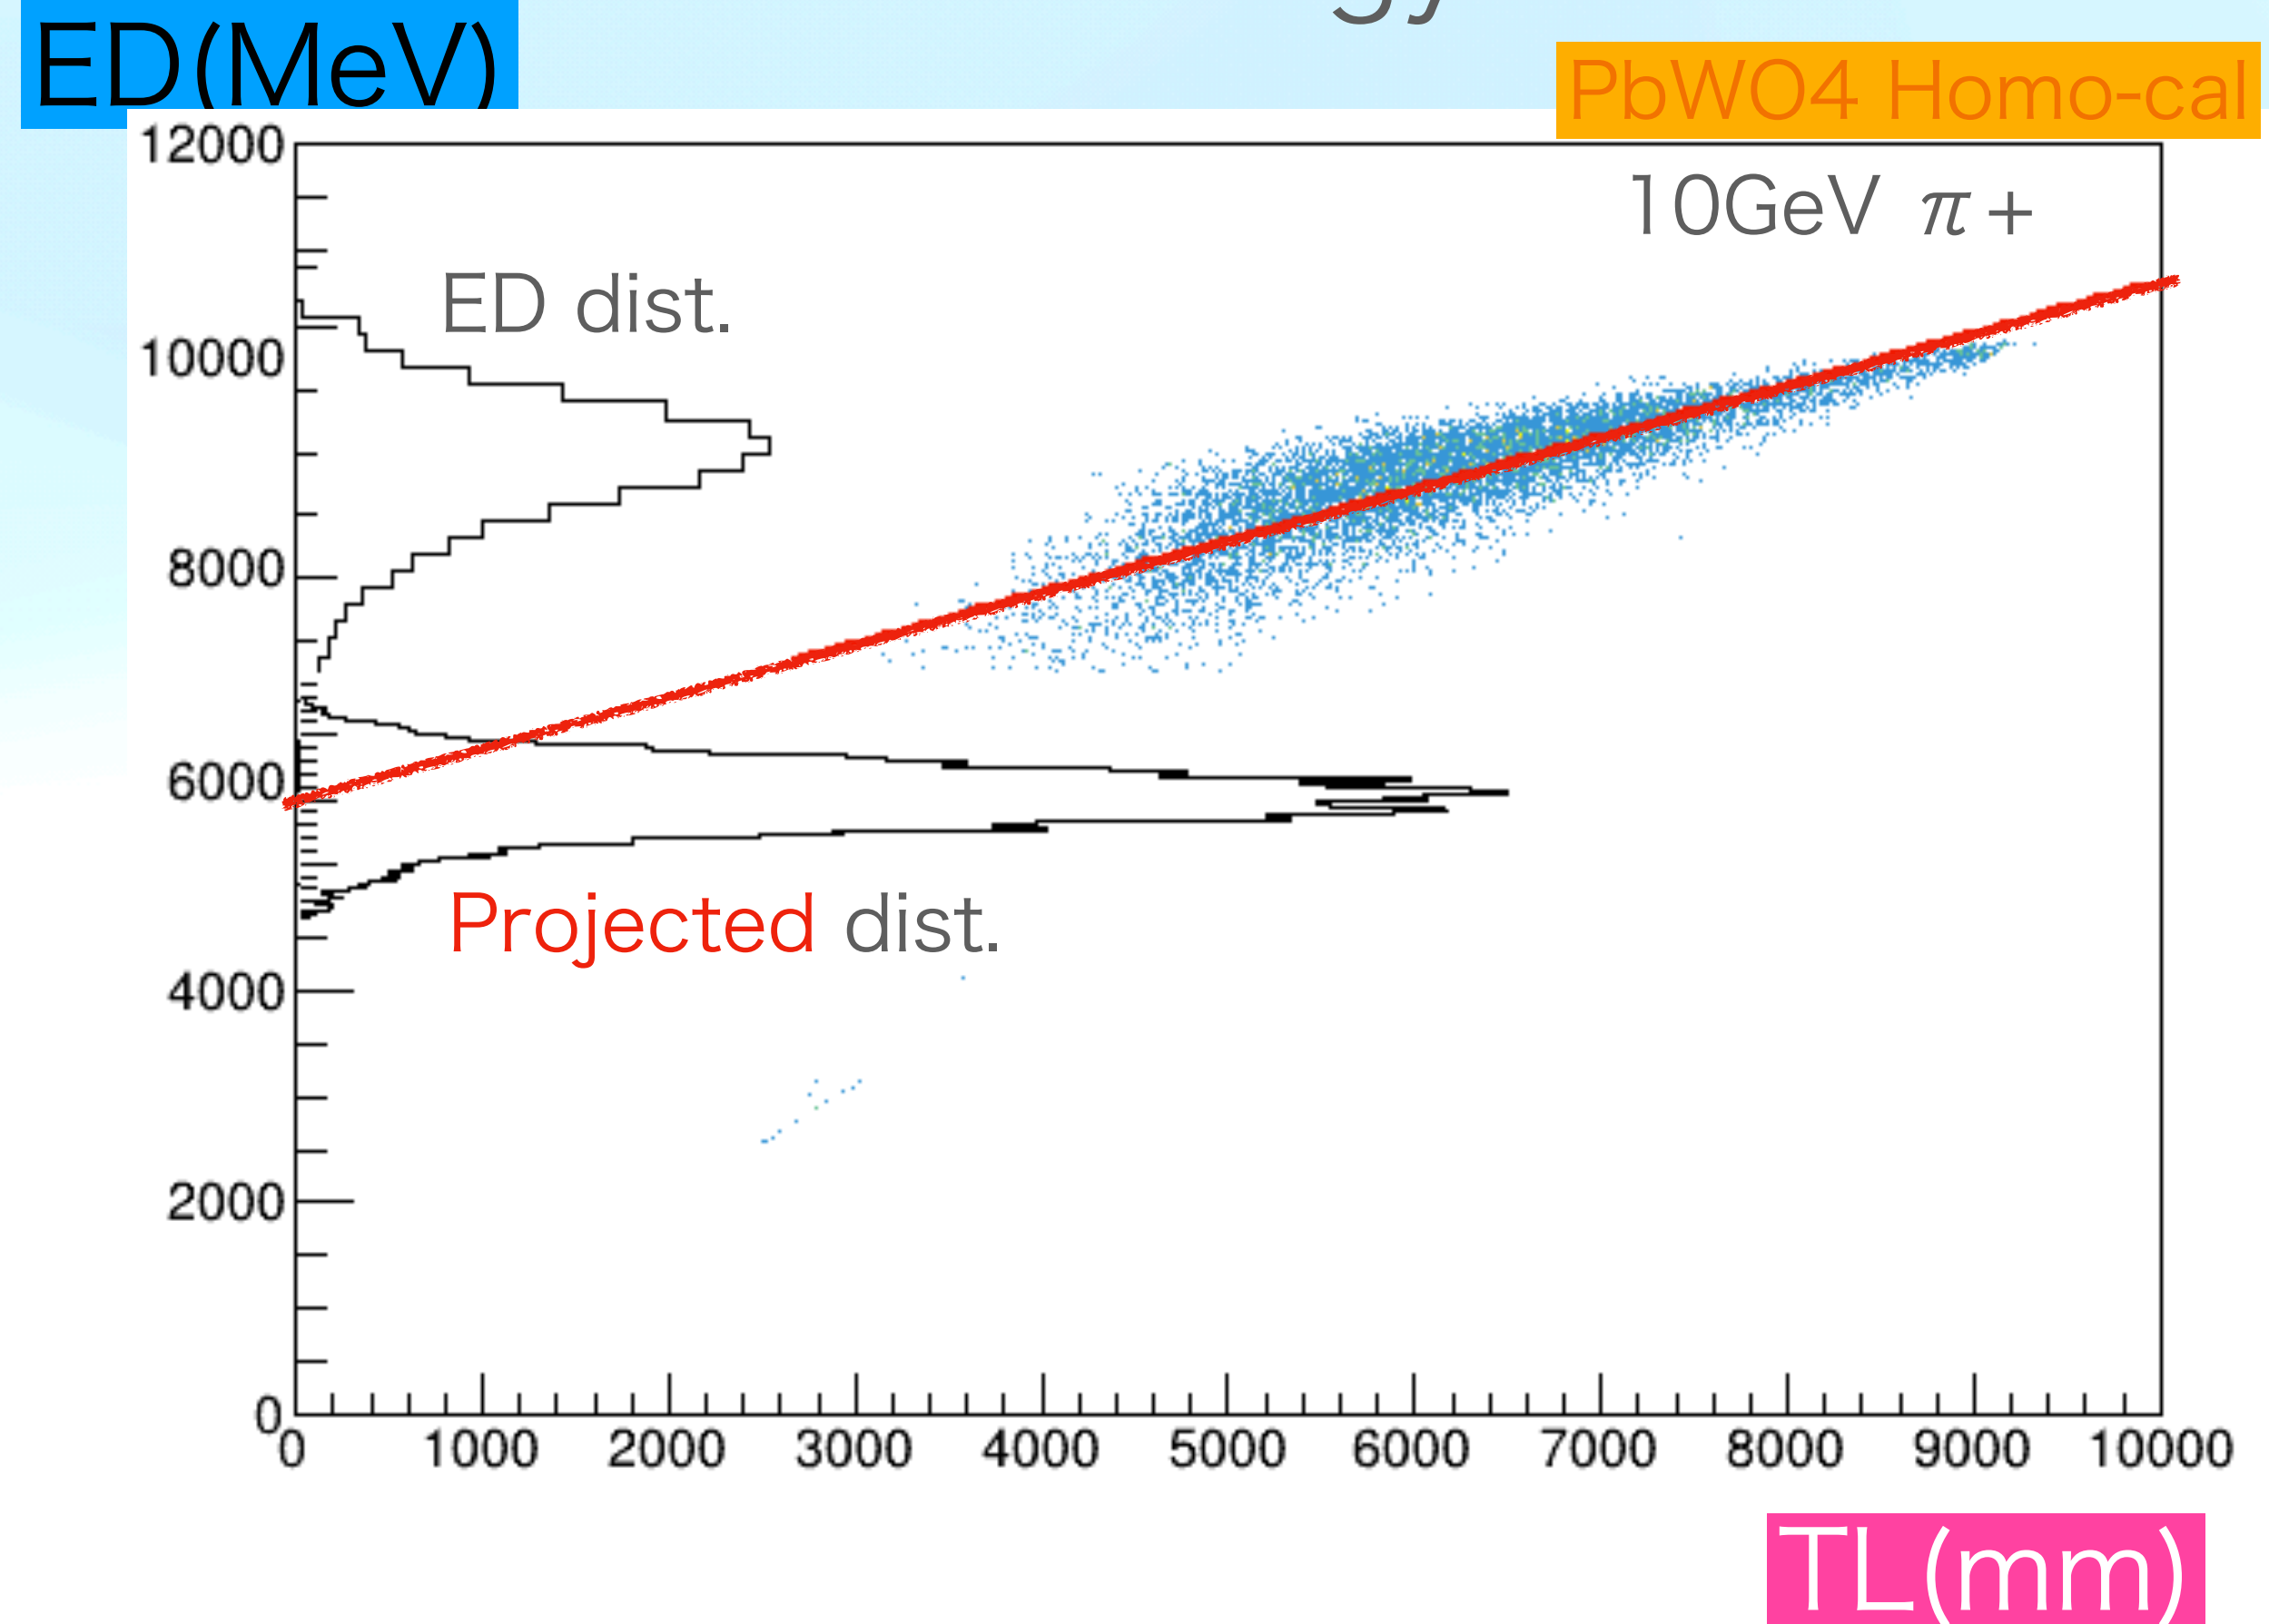

photon statistics is not taken into account  
simulation with GEANT4.10.07with FTFP\_BERT

# energy resolution

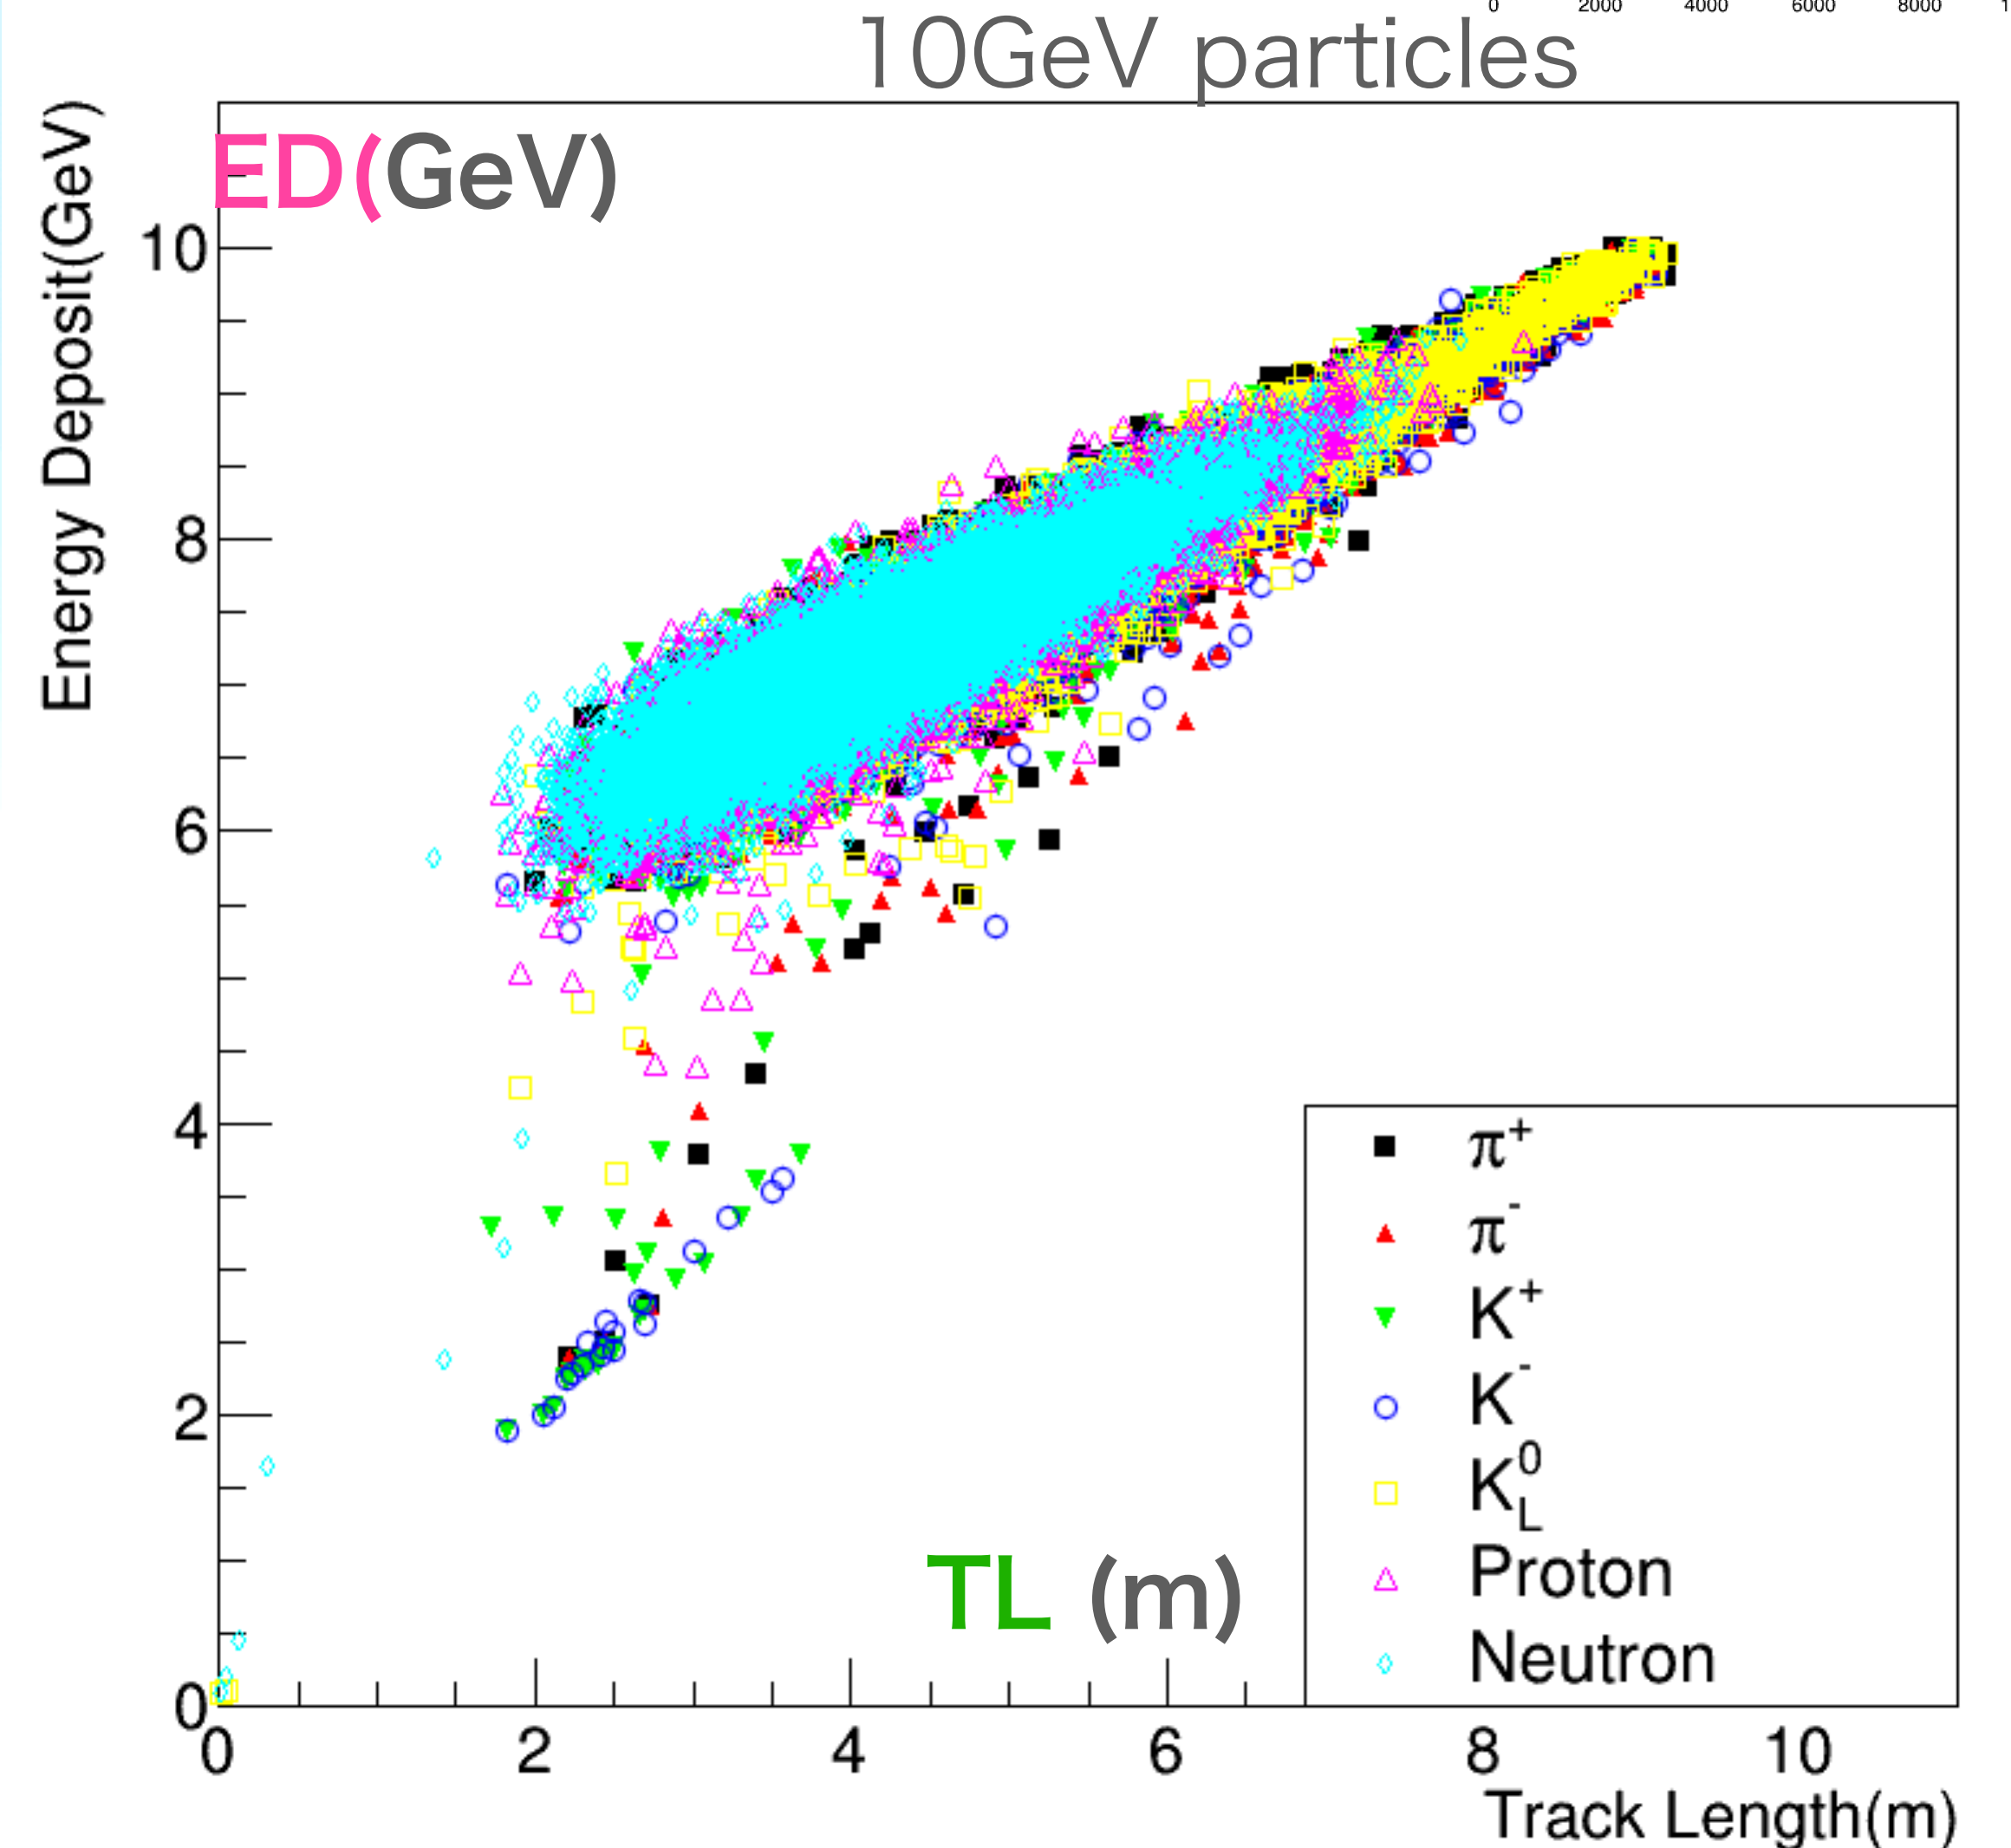

From the correlation plot  
to the energy resolution

- good correlation between ED and TL
- Energy measured by the **intercept**
- energy resolution is expressed by width **projected** to fitted line
- fine energy resolution is achieved than ED distribution

# particle response

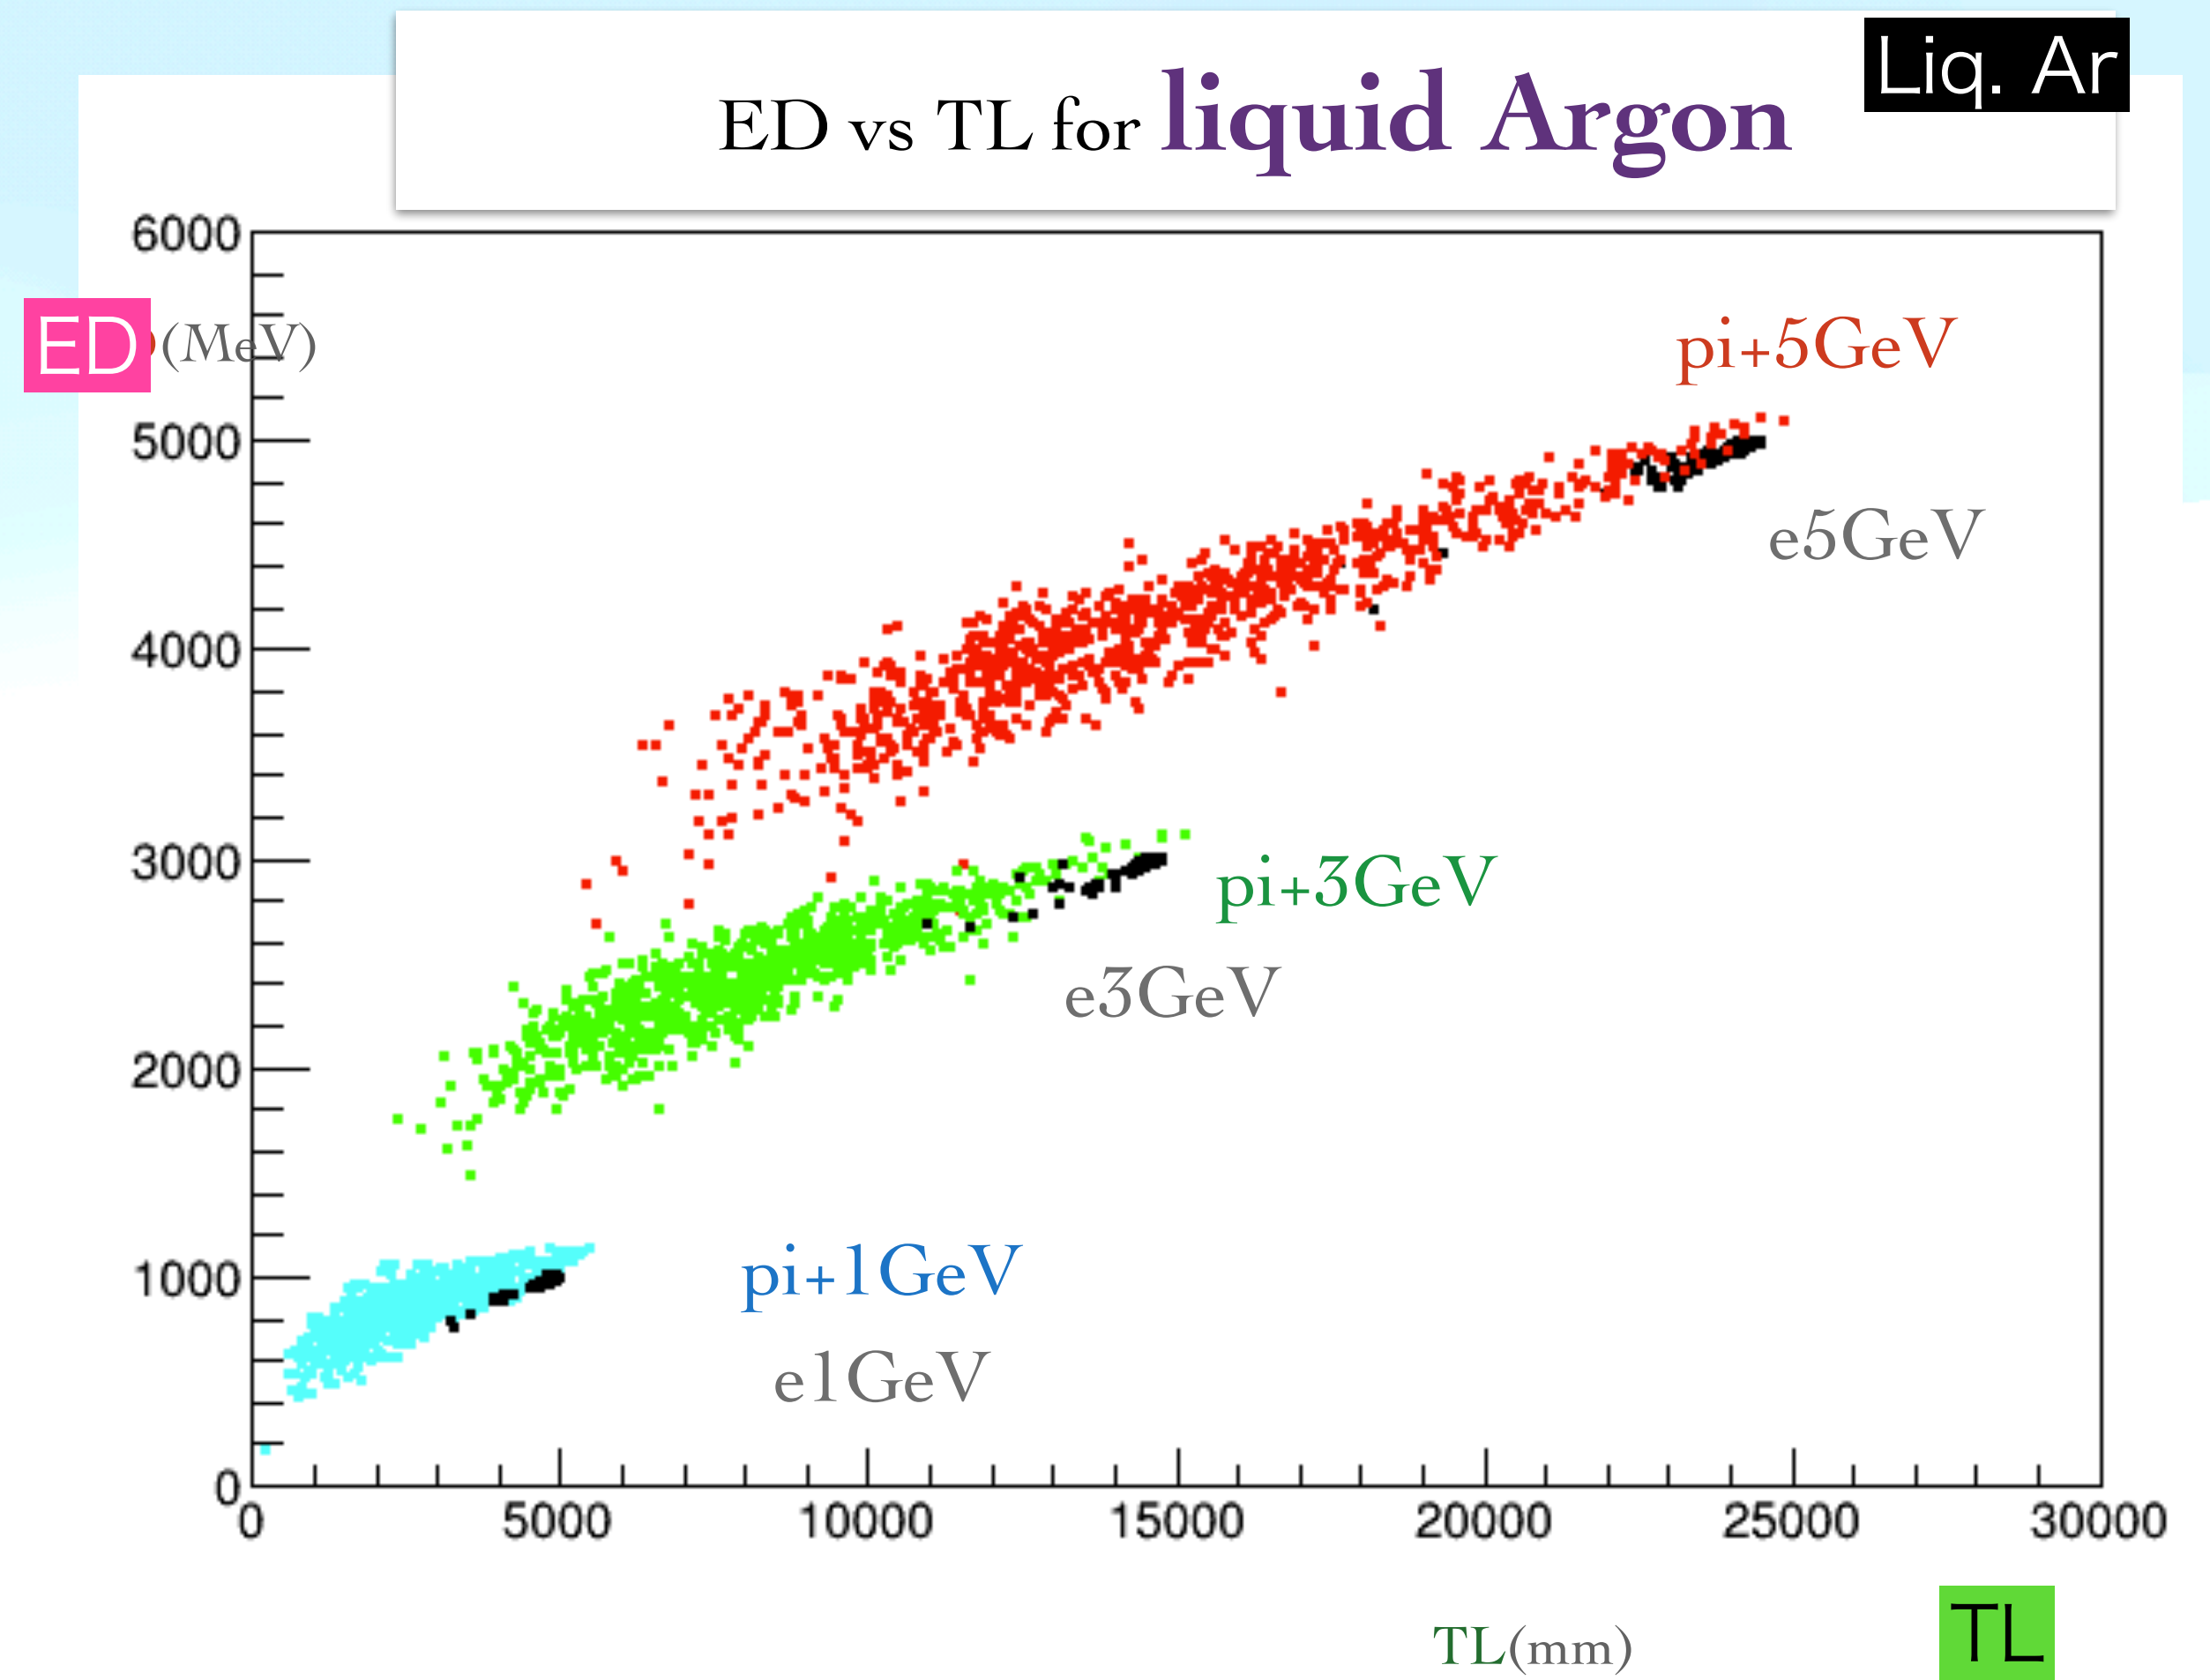

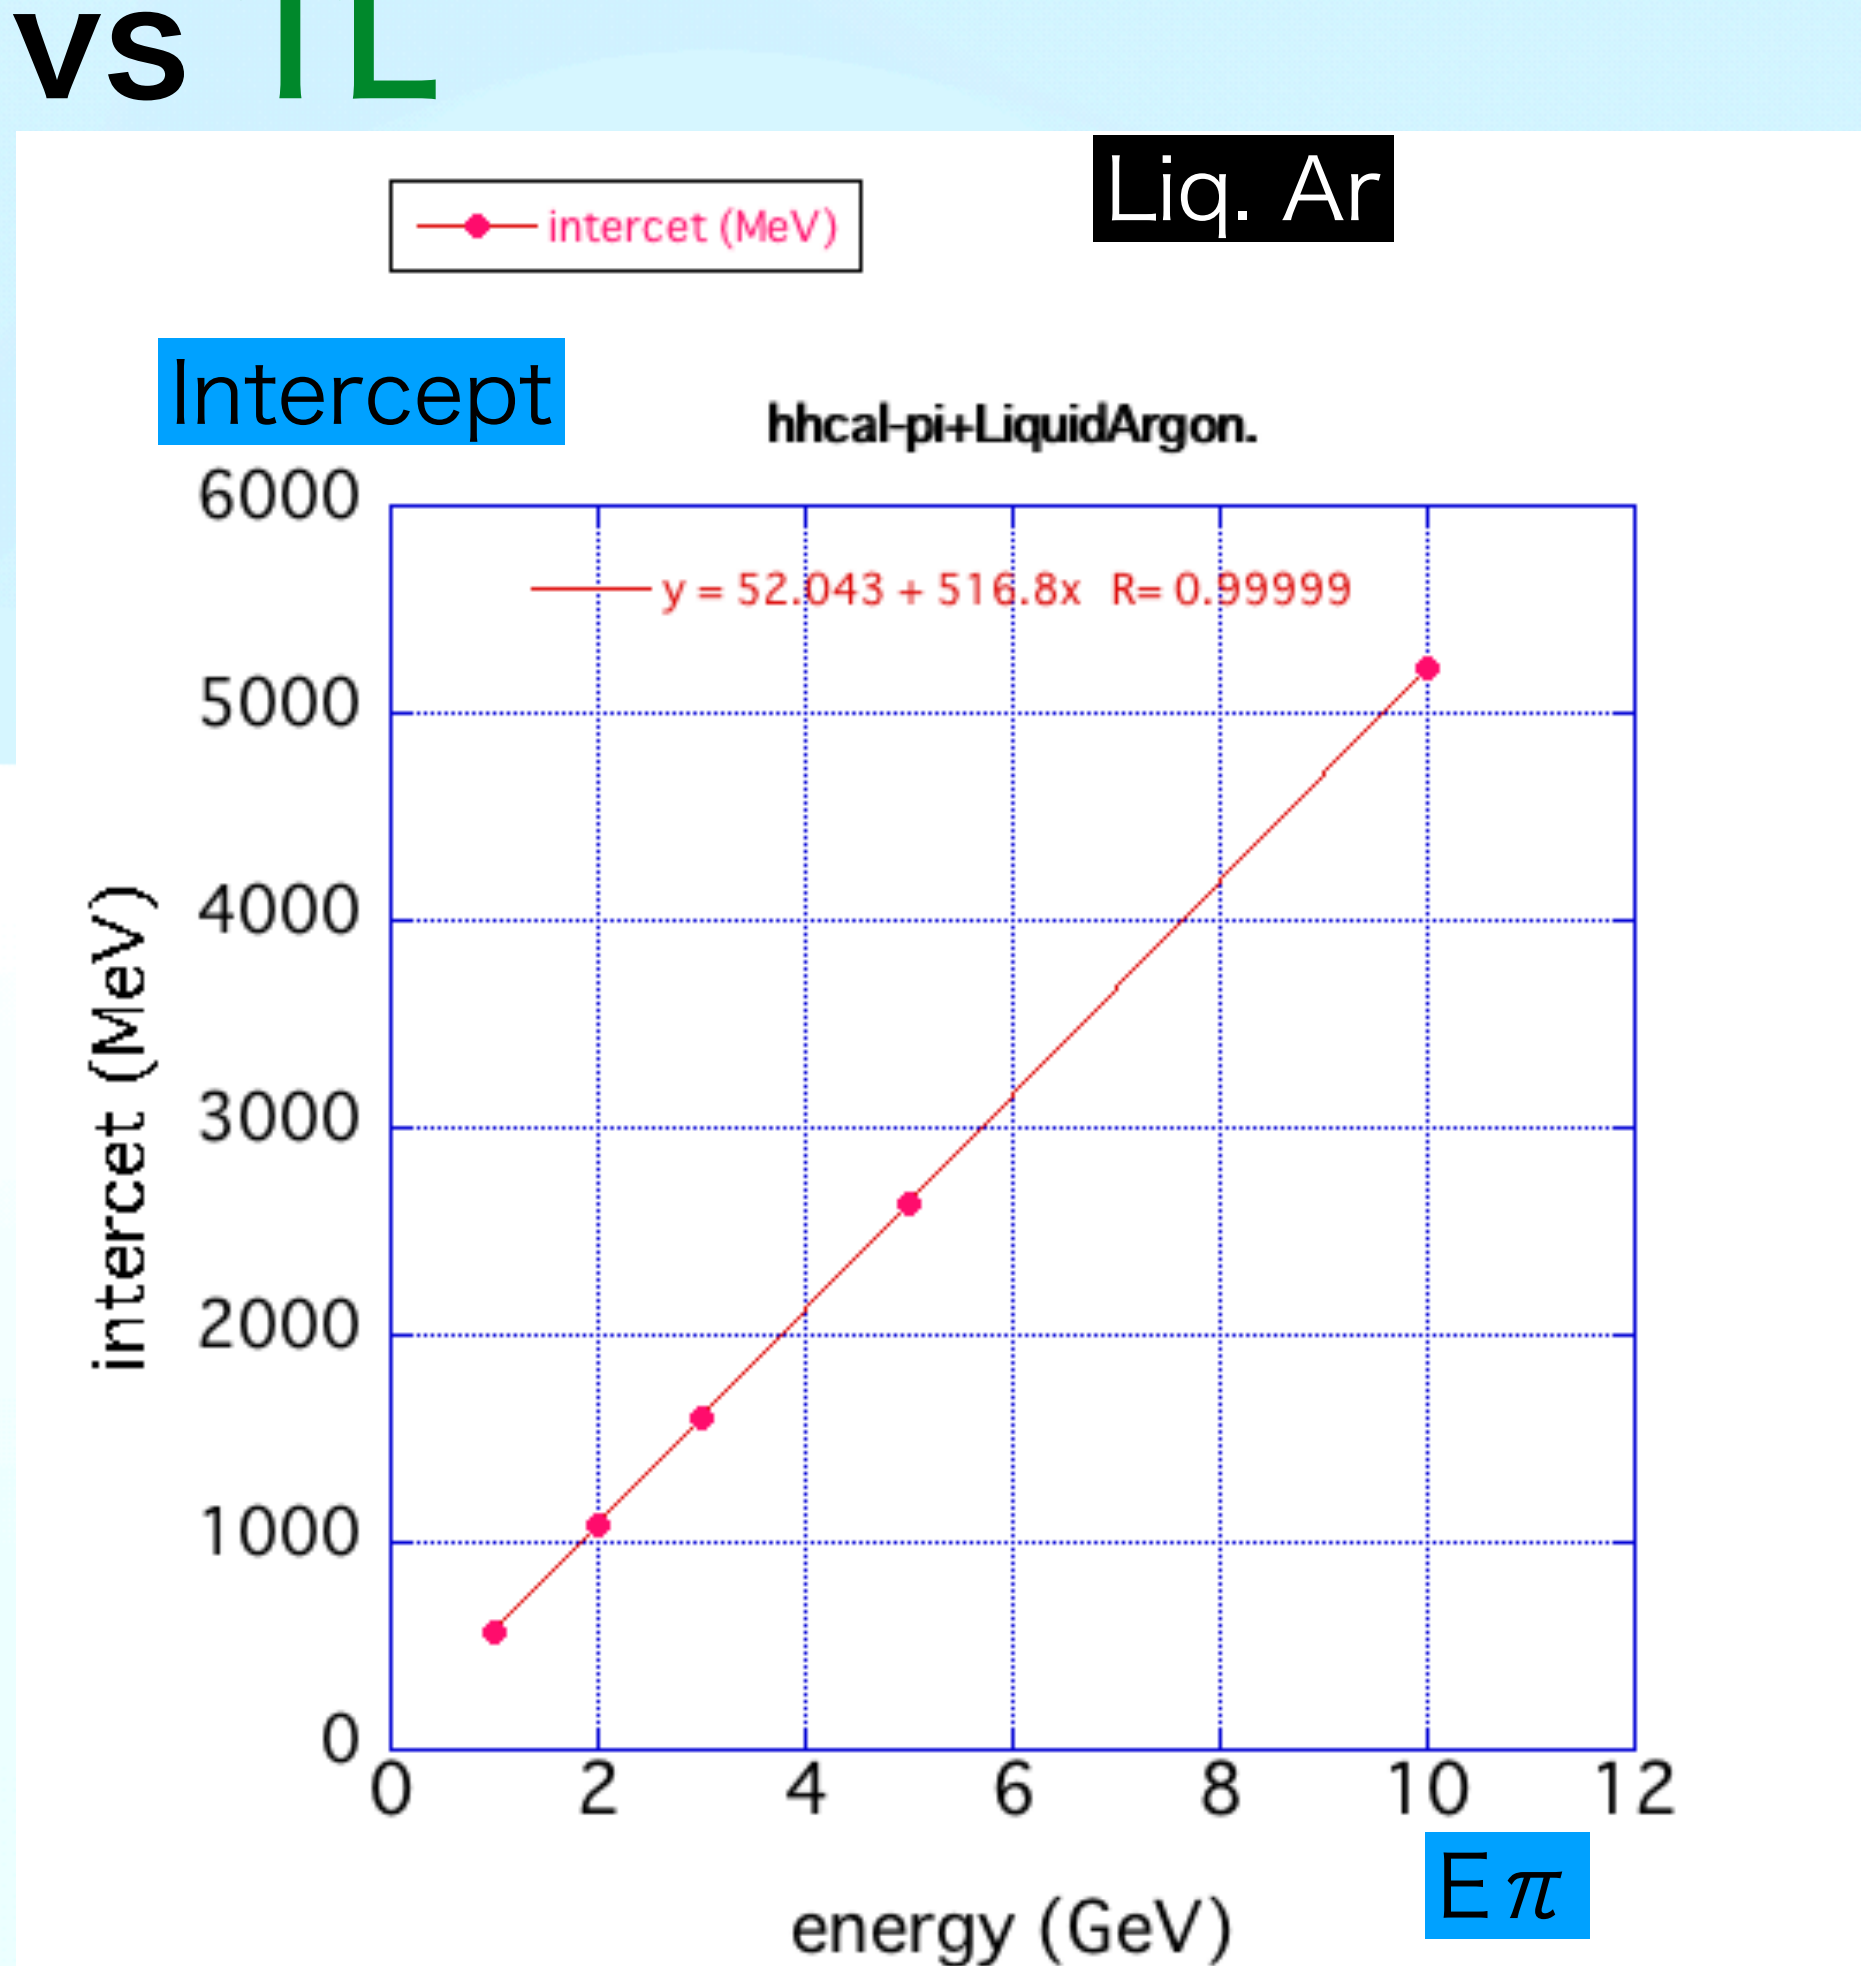

- good linearity with intercept
- slopes are fairly constant
- intercept and slope are **common for particles ( $\pi$ ,K,p,n)**

# Different detector material

Liquid Argon & CsI are simulated

ED vs TL

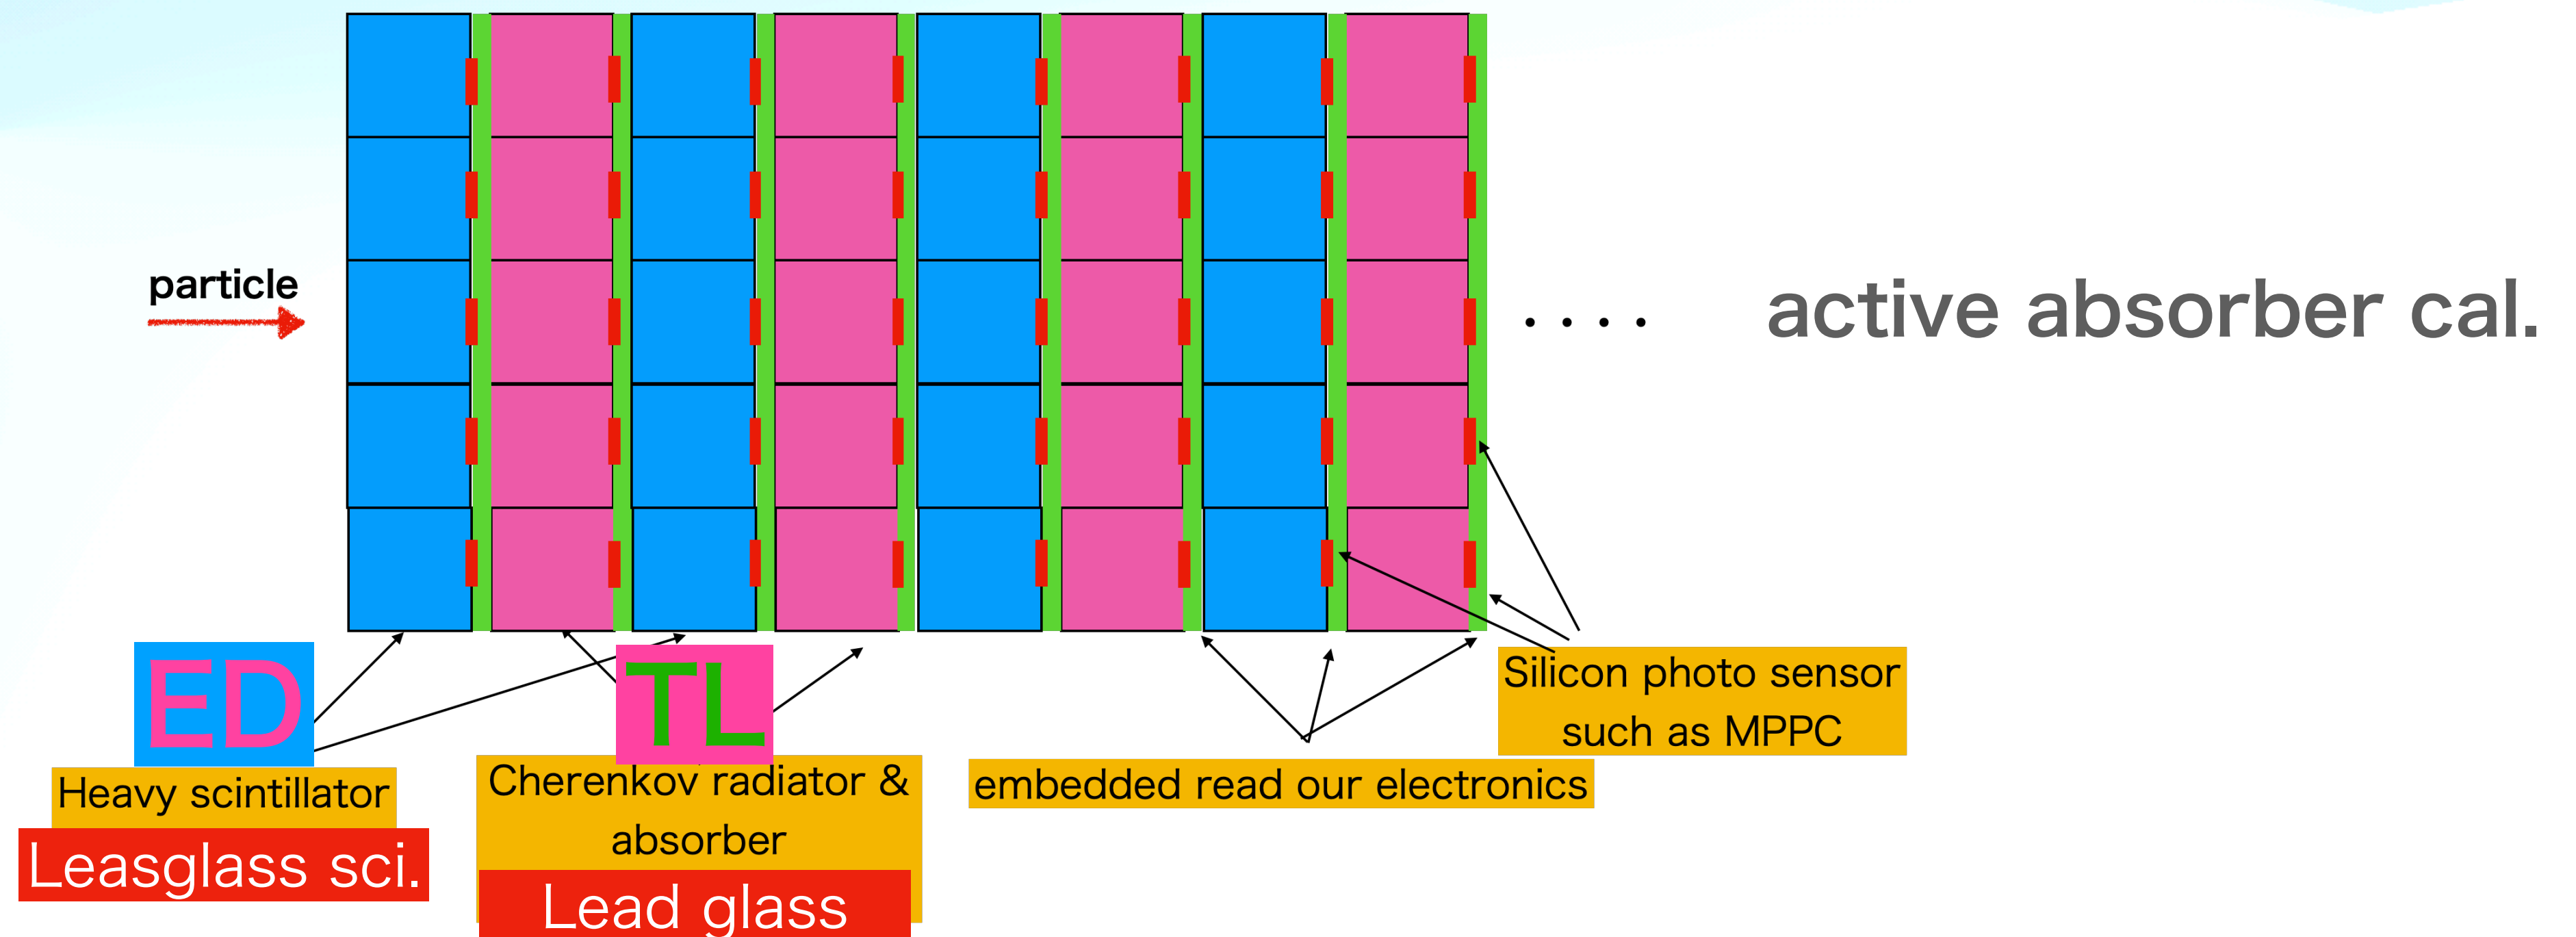

# a **new** idea :Double readout Sandwich Calorimeter of **glass**

- separate Cherenkov radiator and Scintillation material with sandwich style coupled to highly granular option of PFA
- fully active and clear separation of Cherenkov and scintillation lights

Segmented in three dimensions according to the physics requirements

Double  
readout  
Sandwich  
Calorimeter

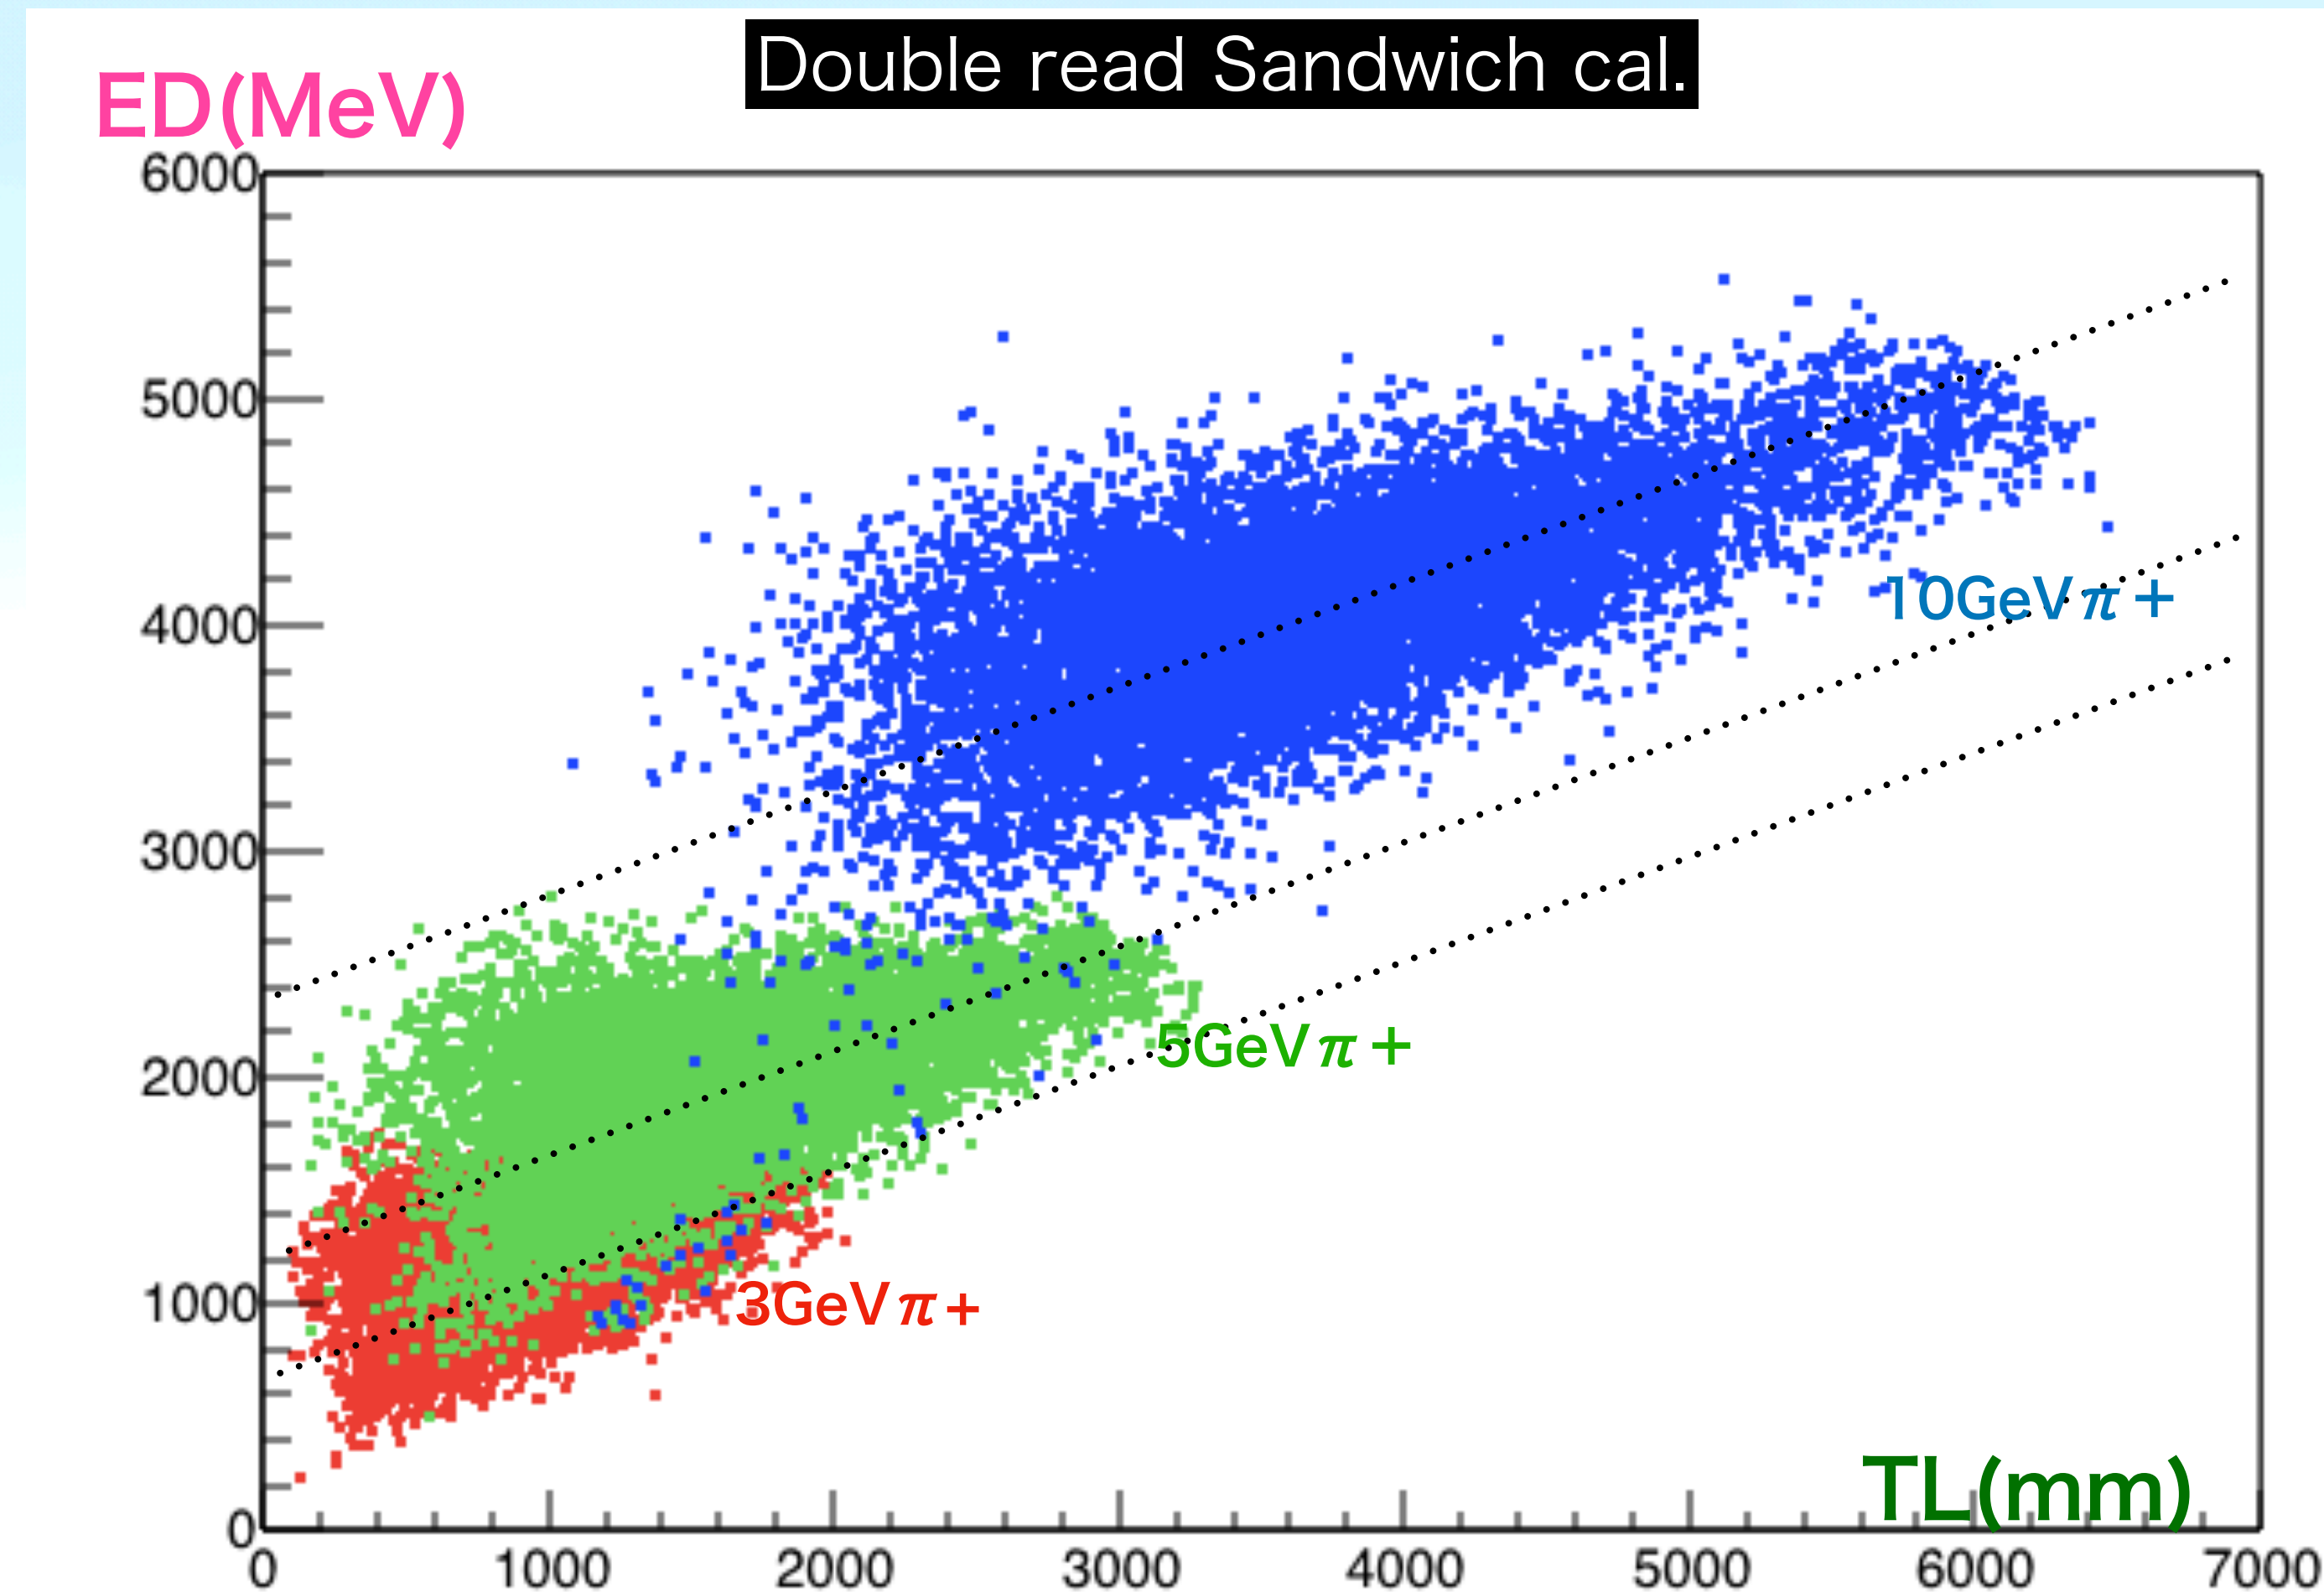

# performance of DSC

(2mx2mx2m cal)

Double read Sandwich cal. simulation

- ED vs TL relation holds for sandwich calorimeter
- **LG2cm+LGSci.2cm**  
50layers
- distributions are wider than homogeneous cal.
- sampling fraction is **0.5** while Homogeneous cal. =1

# Energy resolution of DSC

~ **27%**/ $\sqrt{E(\text{GeV})}$  with **DSC** for **hadrons**

- **close** to **homogeneous cal.**
- **todo**
  - remove **punch through**
  - **prototype optimization**
  - **effect of photon statistics**

# Energy resolution of DSC

~ **27%**/ $\sqrt{E(\text{GeV})}$  with **DSC** for **hadrons**

- **close** to **homogeneous cal.**
- **todo**
  - remove **punch through**
  - prototype optimization
  - effect of photon statistics

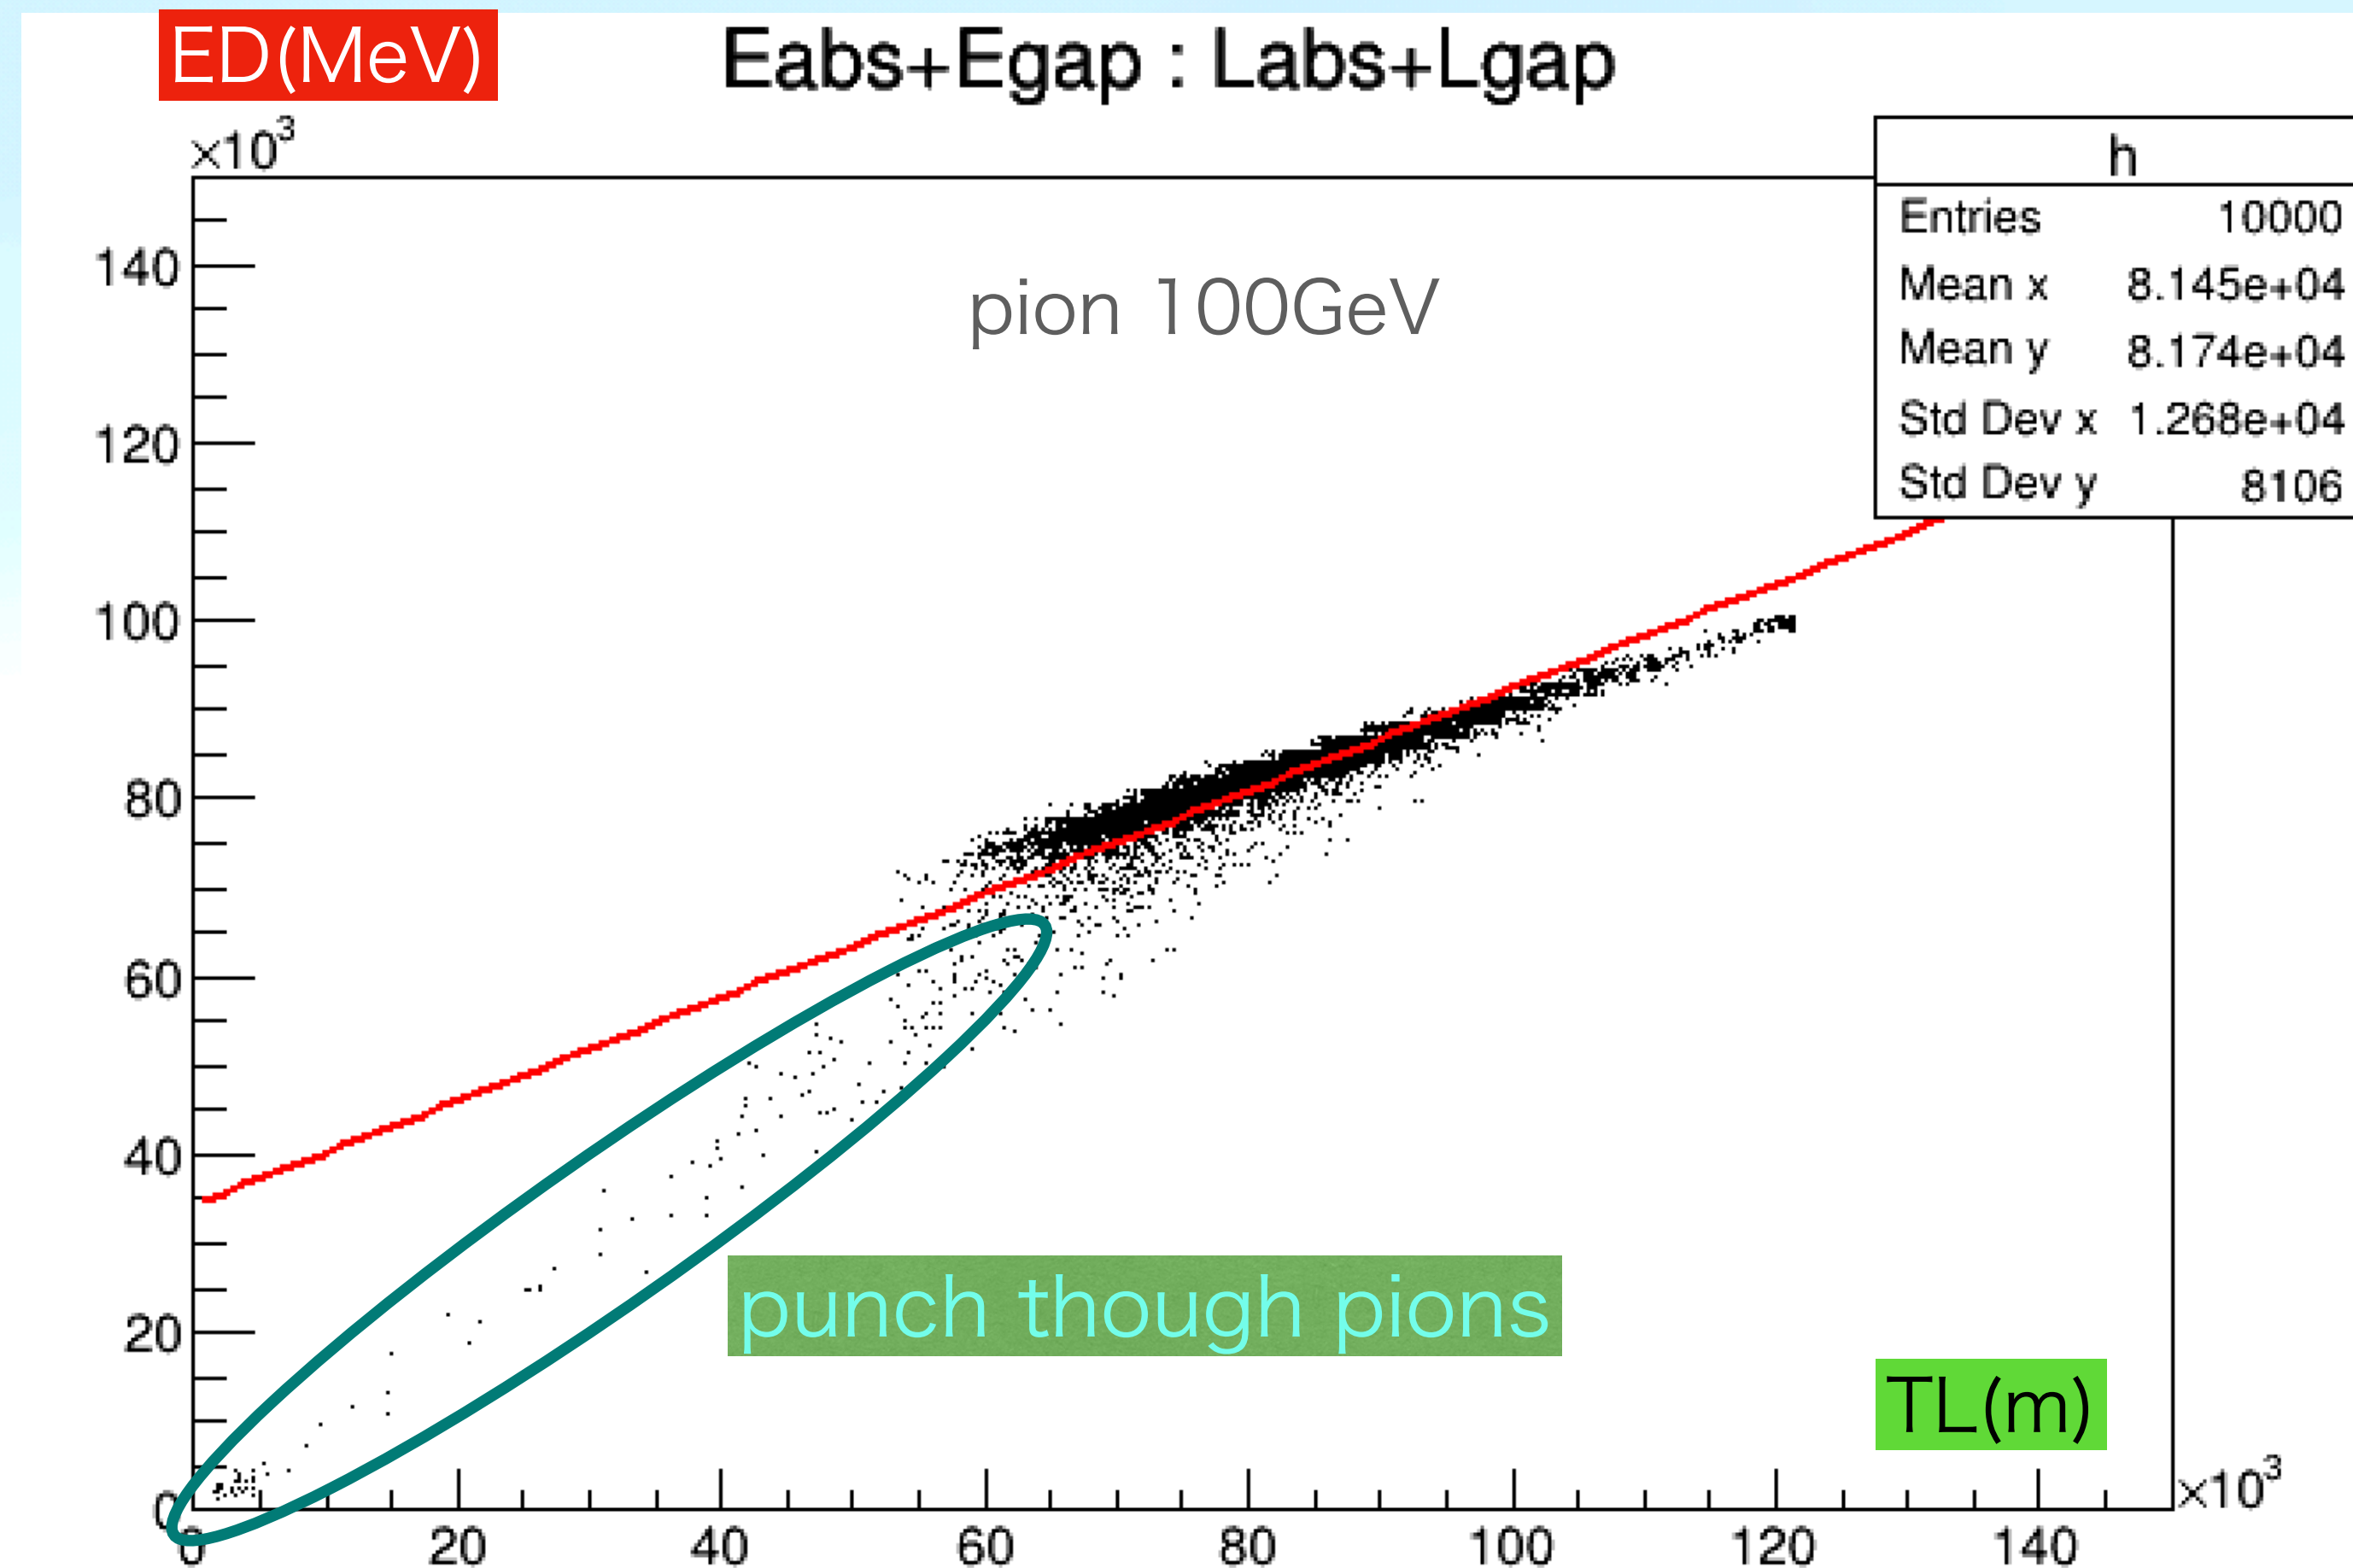

# effect of punch through pions

naive straight line fittings are not representing the distribution

- fitted line in **red** ends up not accurately representing the distribution
- naive linear fitting is affected by low E events
- due to punch through pions
- in this analysis, I did nothing to remove those events

deteriorate line fitting

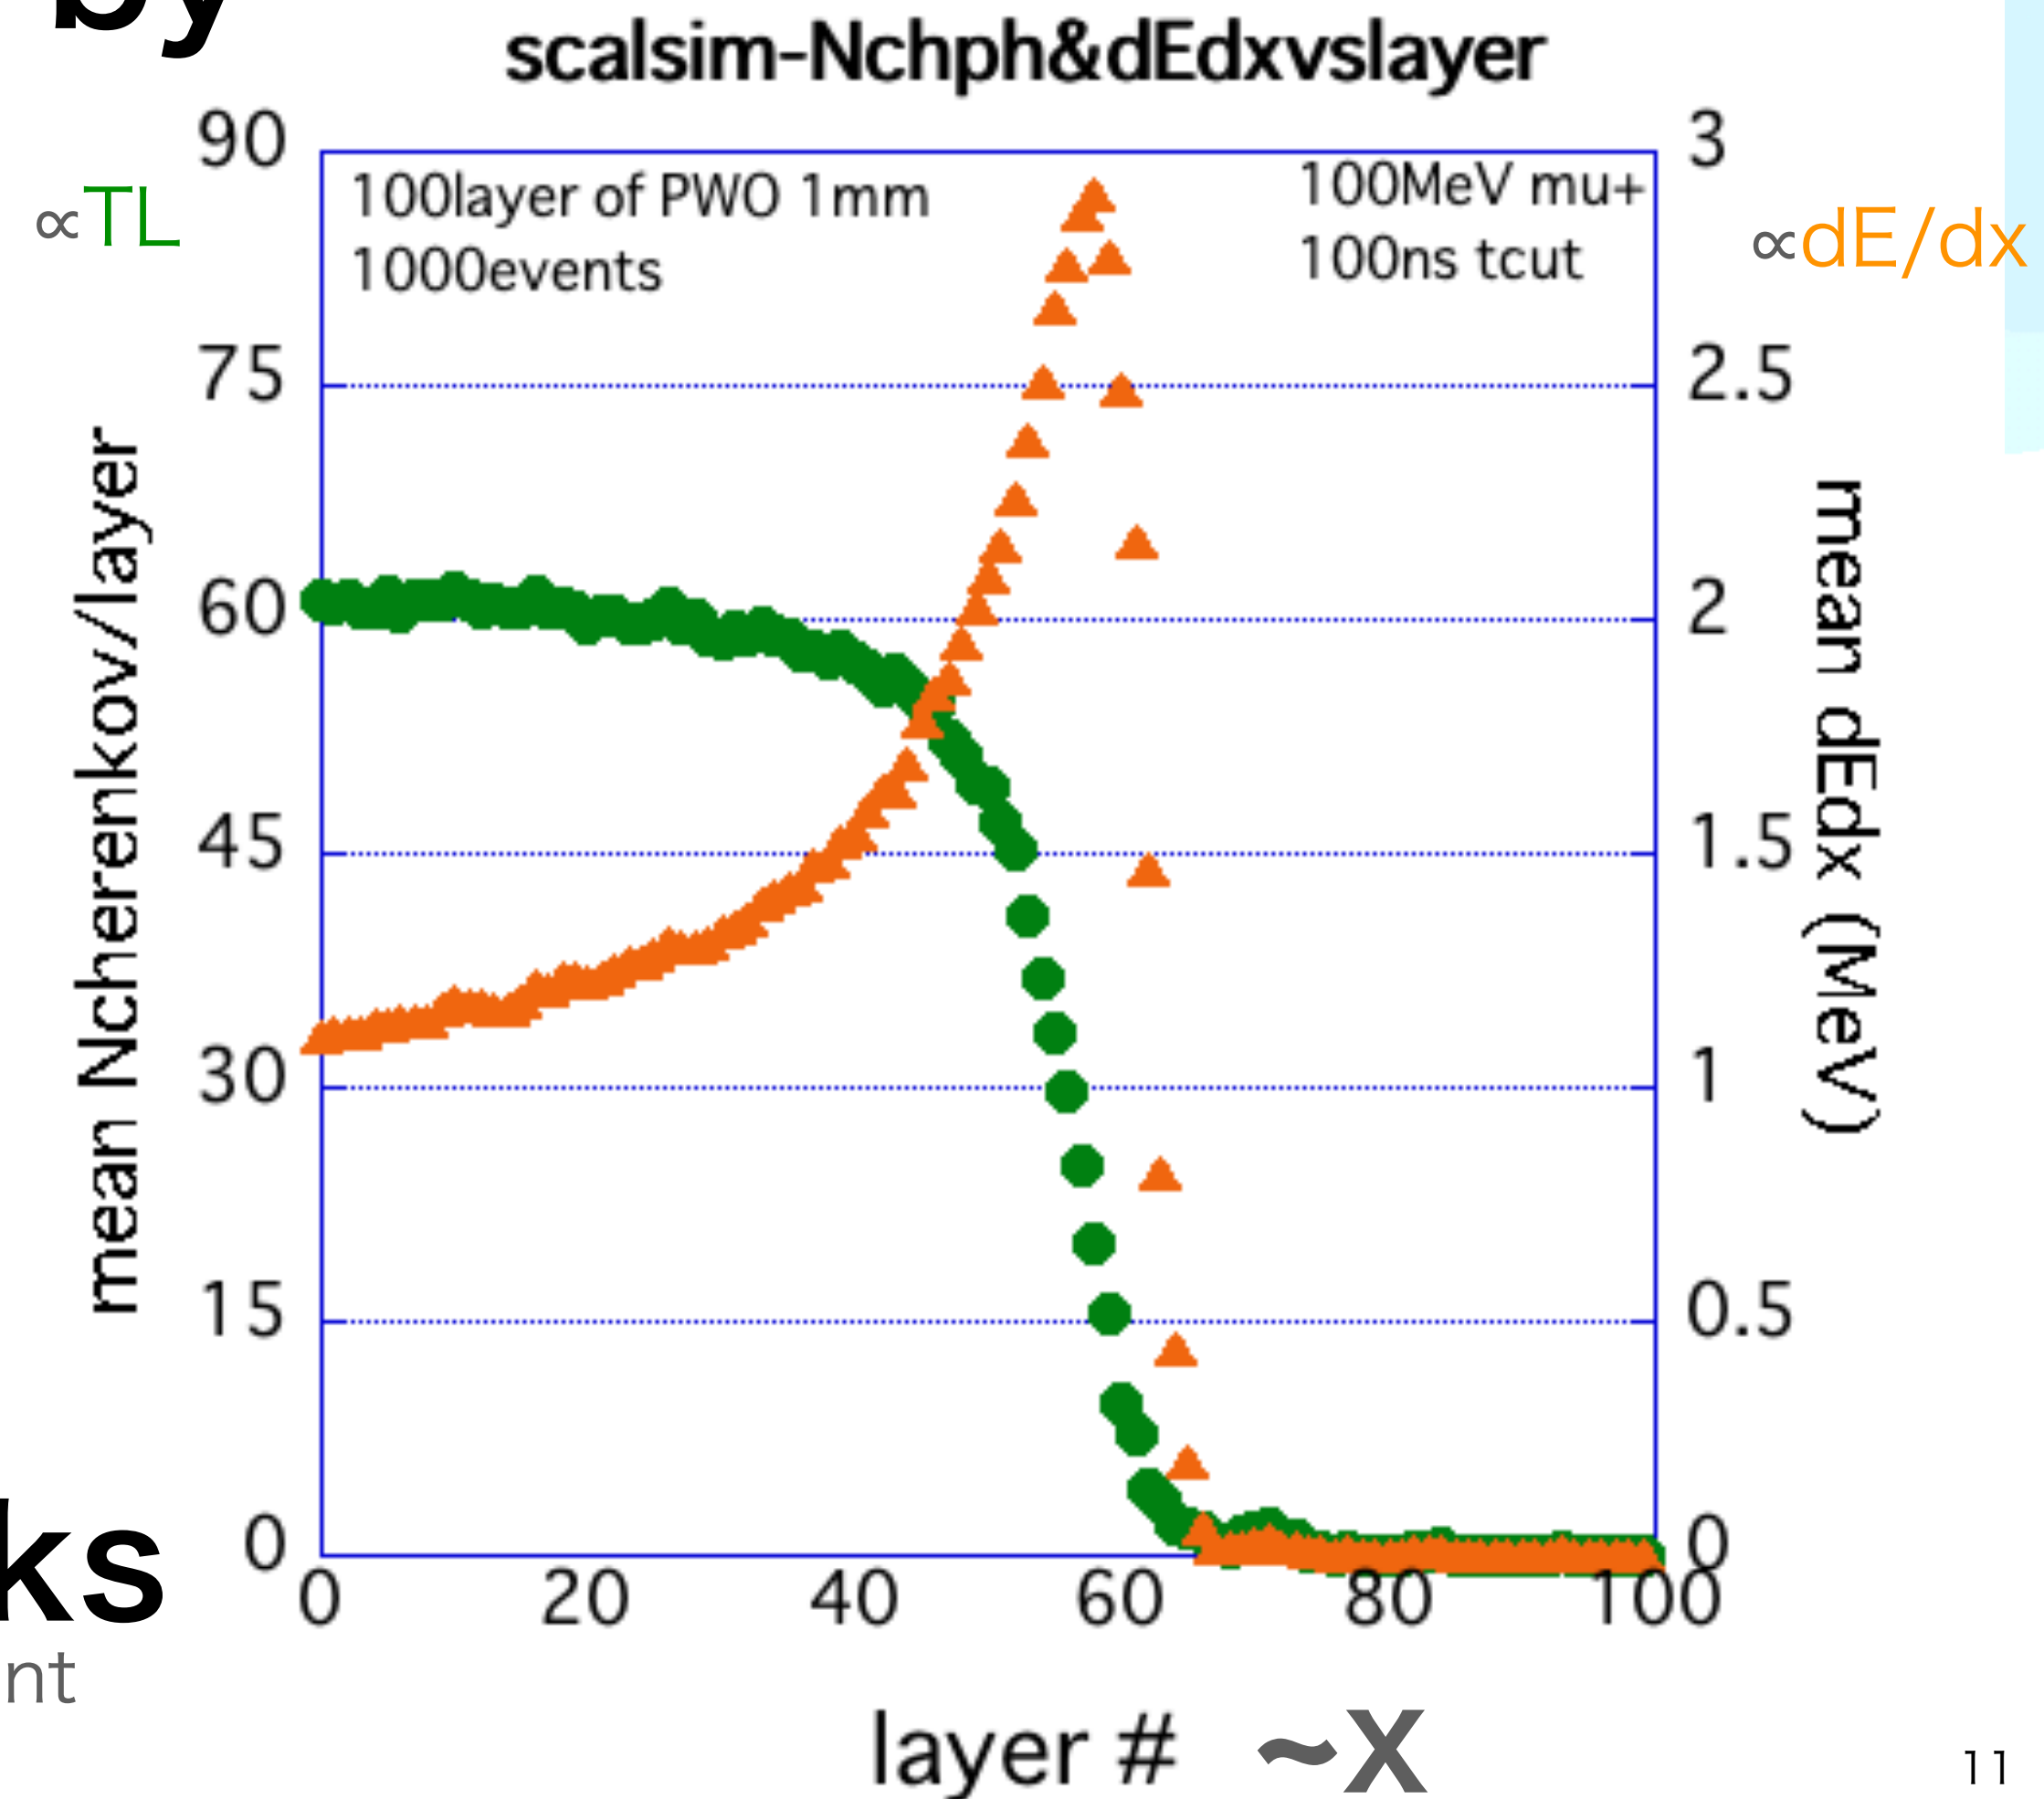

# reason of intercept

when a particle **stops** in a shower

- **Bragg peak** will be detected by only scintillator
- **no peak for Cherenkov**
- Cherenkov threshold exists
- **intercept** corresponds to counting the number of stopping particles when they release energy as Bragg peaks

no contribution to Cherenkov light measurement

# TL ~ Cherenkov light

$$\frac{dE}{d\omega} = \frac{\alpha \hbar}{c} \omega L \sin^2 \theta$$

Frank-Tamm

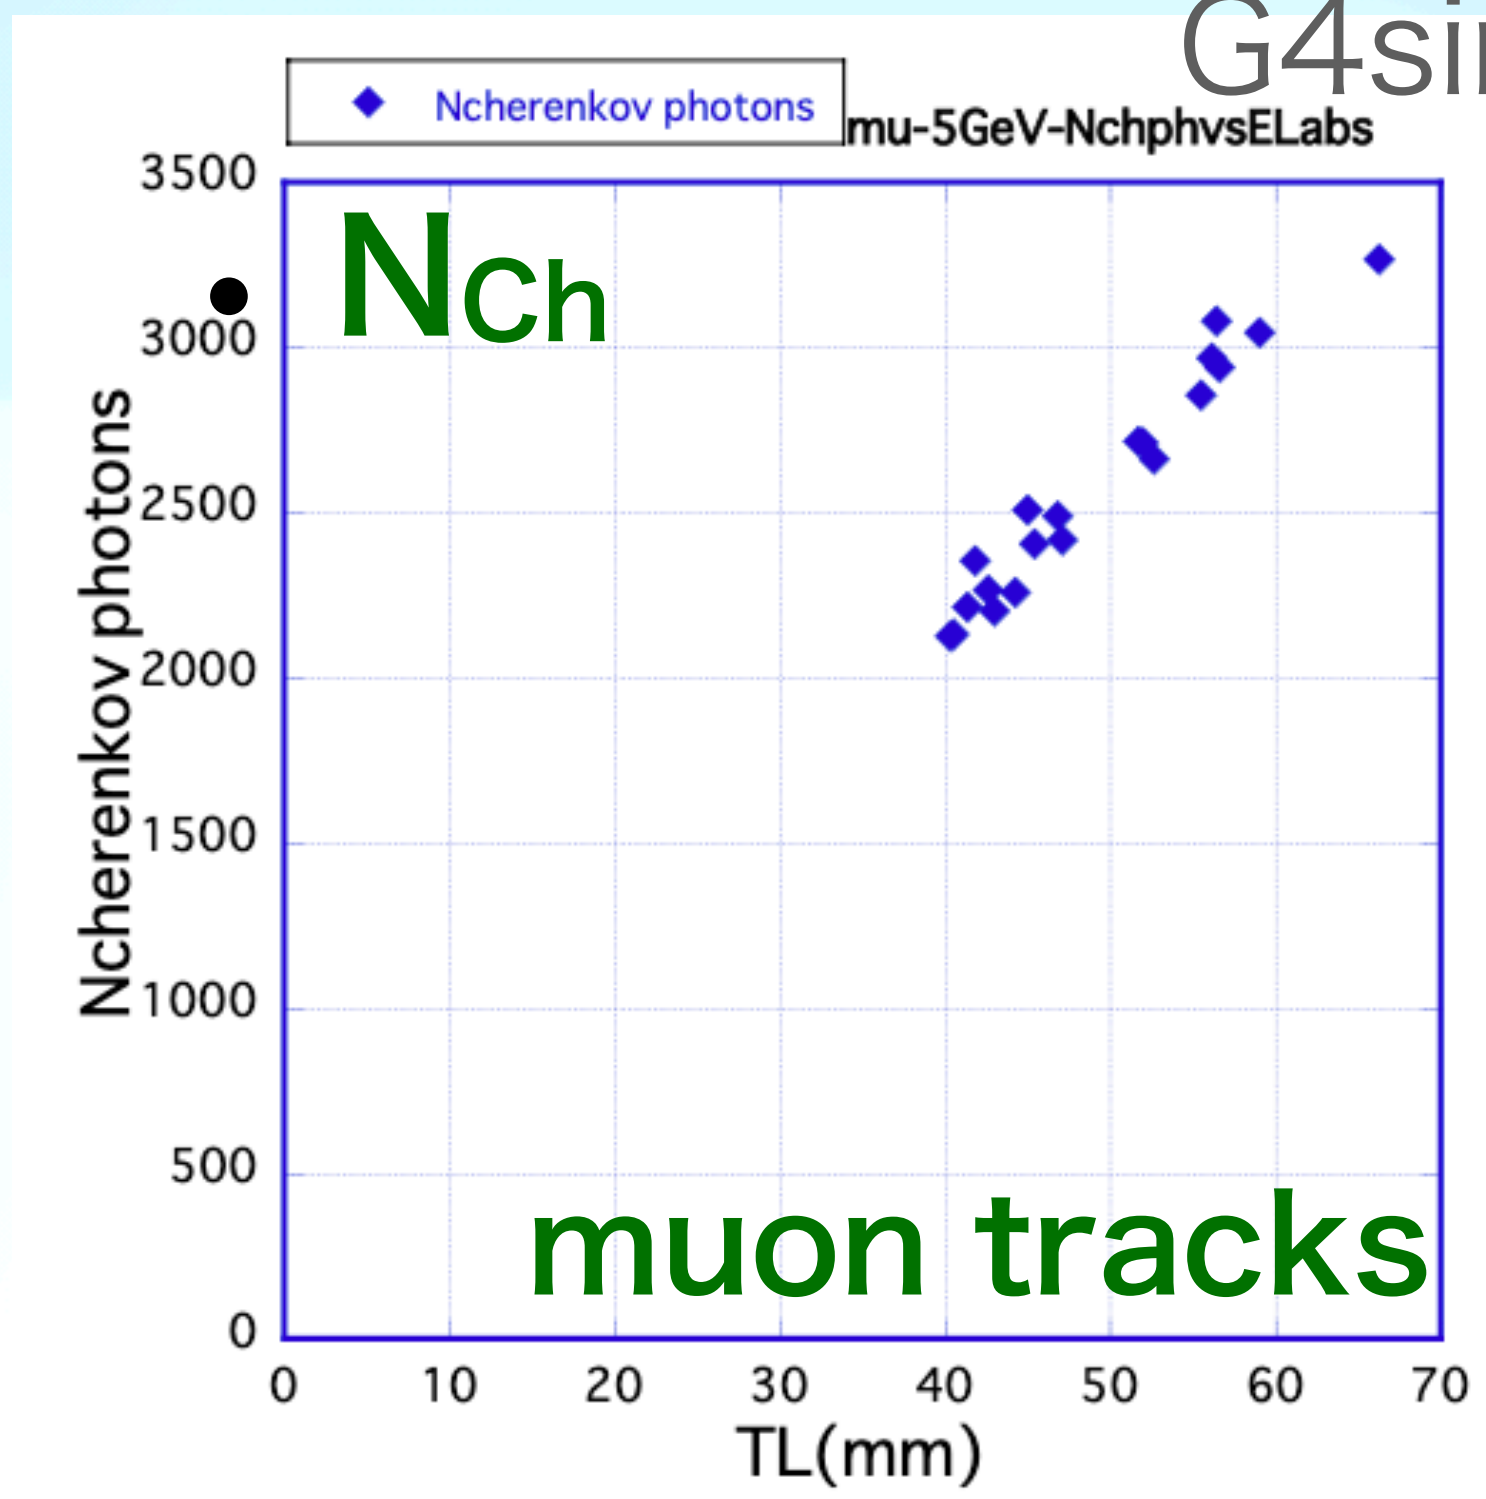

- Cherenkov radiation energy loss

- Cherenkov photons = N

$n(\omega) \sim n$

$$\frac{d^2N}{d\omega dx} = \frac{\alpha}{c} \sin^2 \theta = \frac{\alpha}{c} \left(1 - \frac{1}{\beta^2 n^2}\right)$$

- $N_{Ch} \propto X = TL$

# Feasibility of the DSC

Cherenkov tile will generate small number of lights

- **LG: 2cm<sup>t</sup> x3x3cm<sup>2</sup>** (PFA cal.)

all polished & 1 non-pol.

**grease** coupled MPPCs

UV and normal MPPC

6mmx6mm

- **LY is good for the calorimeter**
- UV light does not transmit in glass
- polished surface can increase collection efficiency

LY(pe)	normal PPD	UV PPD
all polished	12	12
<b>1</b> unpolish	8	8
<b>4</b> unpolish	15	-

timing resolution < 100ps

# summary and outlook

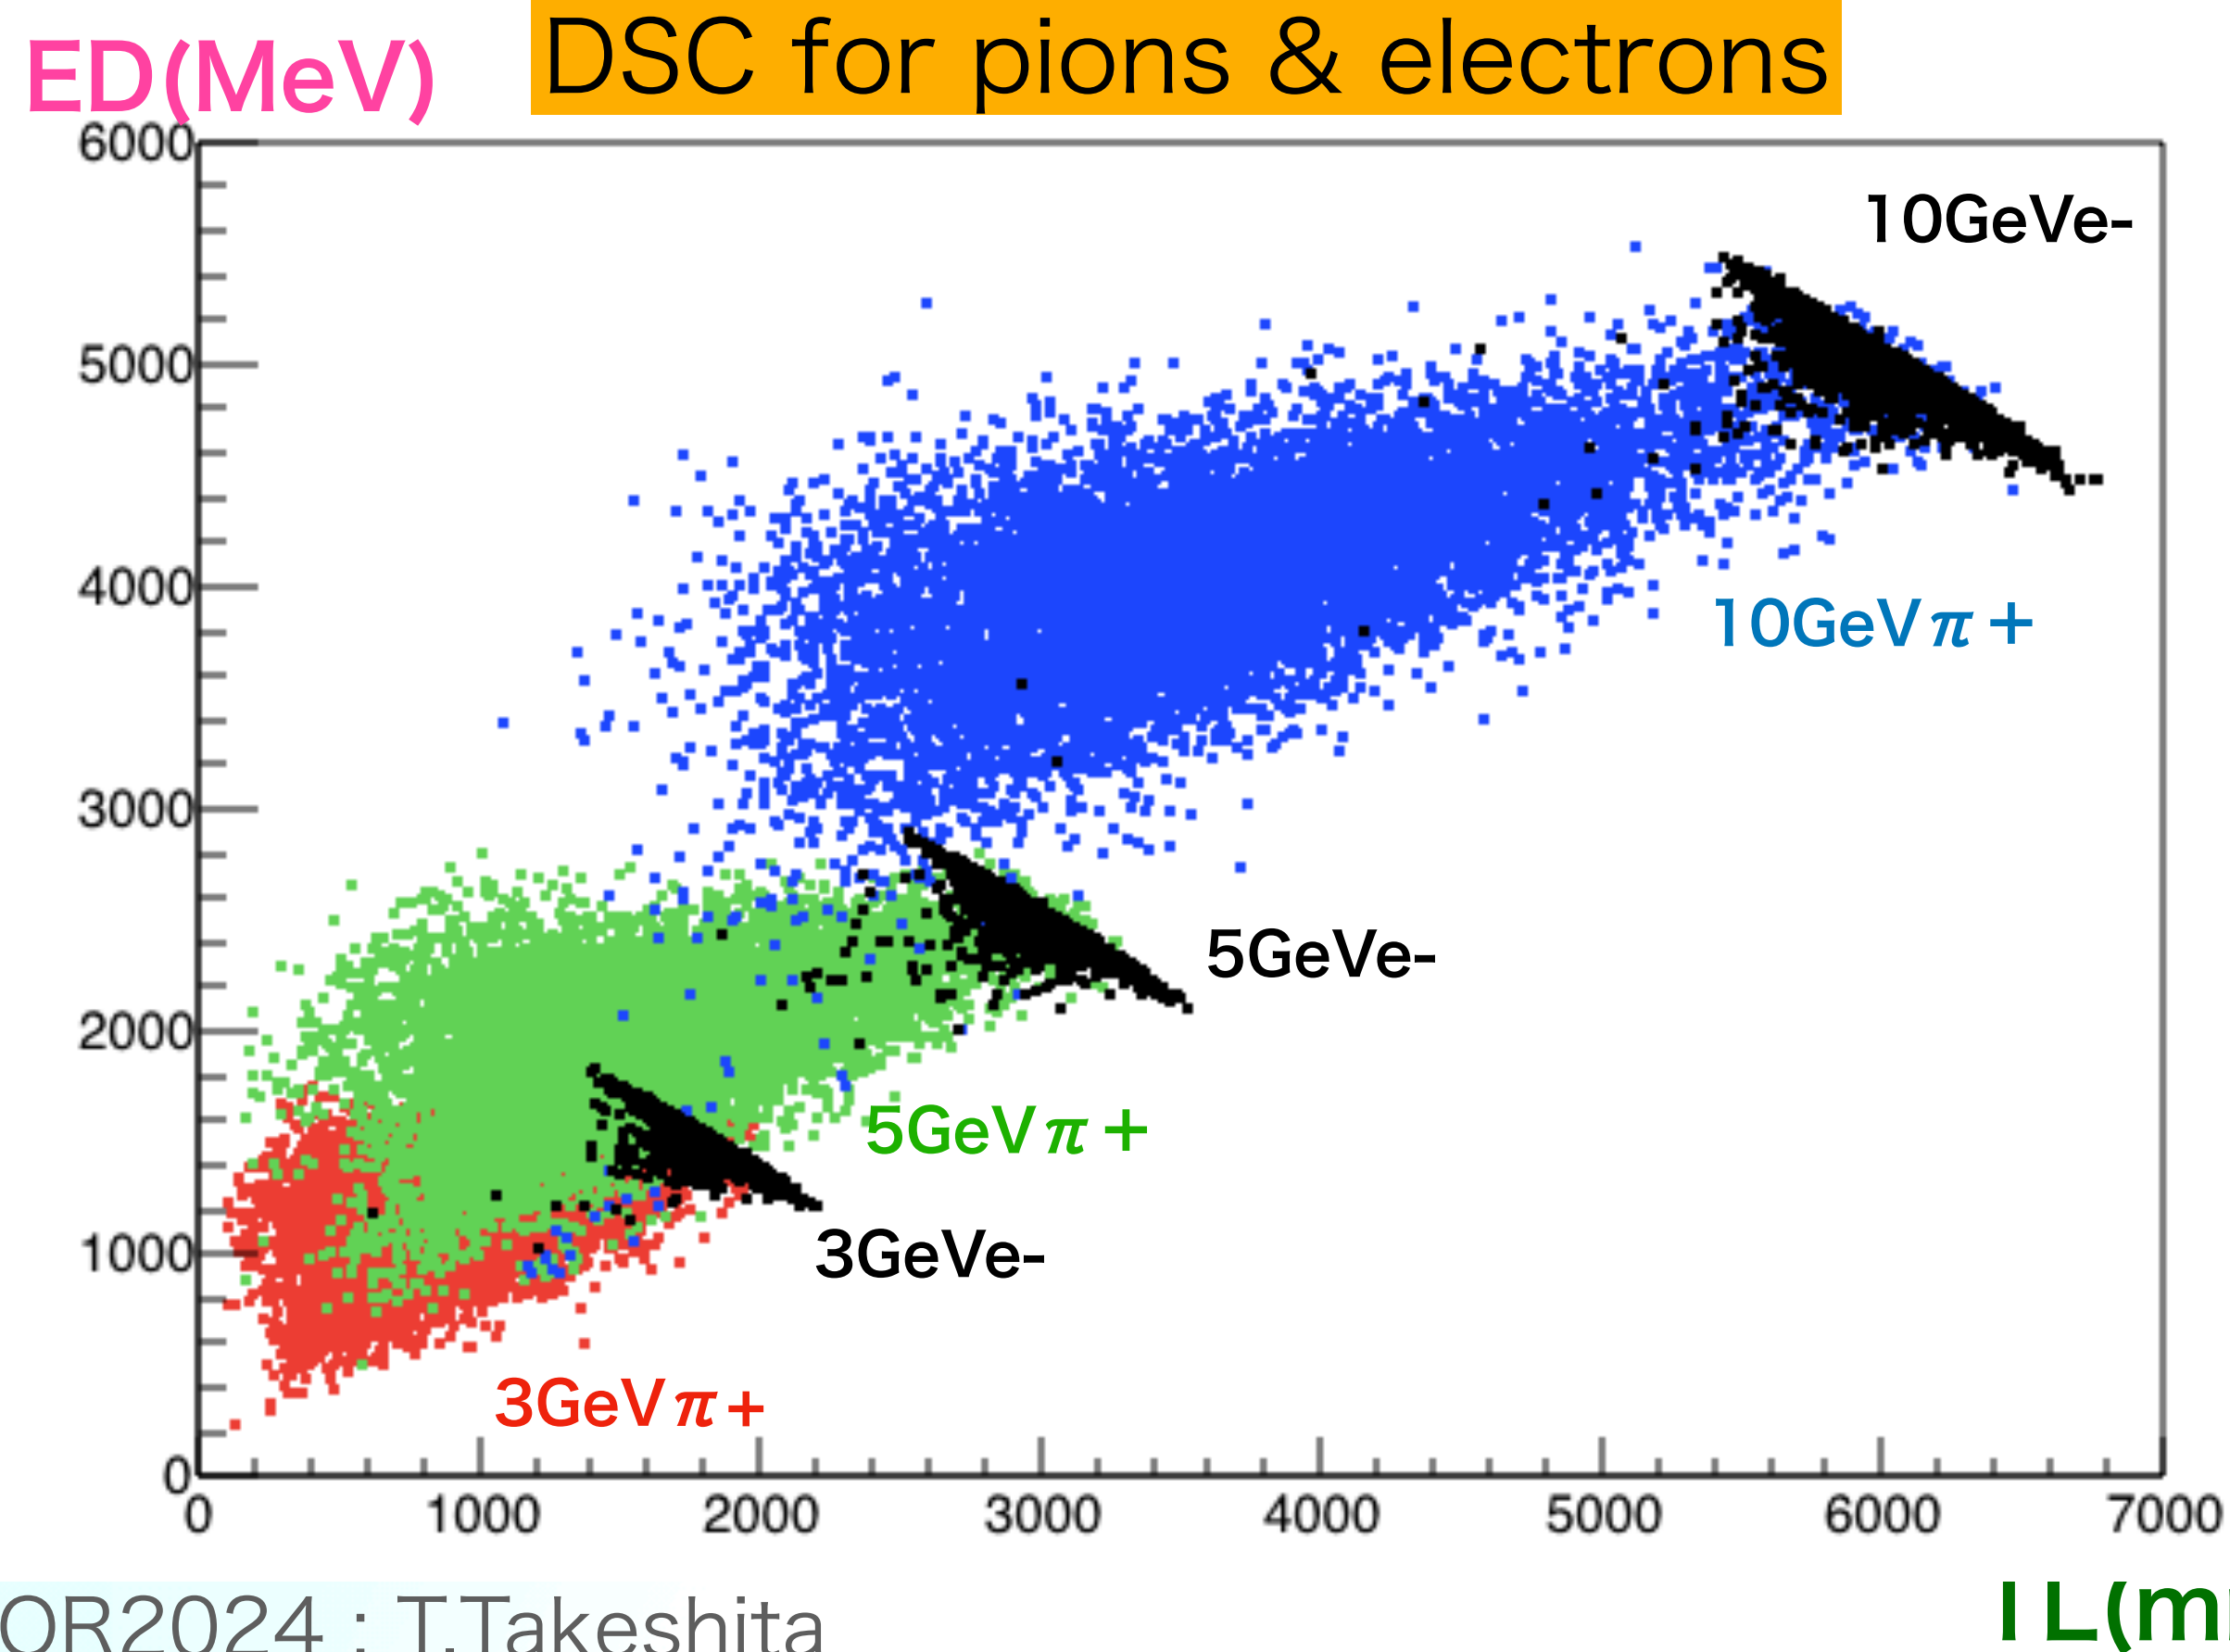

- Double readout **glass** sandwich calorimeter
  - < Homogeneous cal. simulation
- linear correlation between sum of **Track Length (Cherenkov)** and **Energy Deposit** (scintillation) guides studies
- actual implementation is proposed as DglassSC with fine energy resolution
- R&D for DSC is on going
  - how to throw away punch through pions
  - Cherenkov light in the sci-glass
  - production of **scintillating glass** with Quantum Dots

# electrons on DSC

- electron energy resolution
- sum of ED(LG) and TL(LG) = const.  
~  $15\%/\sqrt{E}$

# Separation of Cherenkov & Scintillation light

- scintillator such as PWO generates Cherenkov lights inside as well,
- Cherenkov is dominated in the UV region  $\sim 1/\lambda^2$  (UV)
- UV light will be absorbed and converted to scintillation light
- we count Cherenkov light as scintillation light
- Separation of Cherenkov and scintillation light is not an easy task

PWO optical properties

# DSC

LG 4mm + Plastic Scintillator 8mm  
sandwich calorimeter  
NO correlation  
need **heavier** scintillator
