Summary

The ternary $\text{A}_{1-x}\text{M}_x\text{Fe}_2\text{As}_2$ ($\text{A}=\text{Ca}, \text{Sr}, \text{Ba}$ and Eu ; $\text{M}=\text{K}$ and Na) were found to have similar structural, magnetic and superconducting properties with the related $\text{RFeAsO}_{1-x}\text{Fx}$ [1]. The $\text{Ca}_2\text{Fe}_2\text{As}$ undergoes a first-order high-temperature h-T tetragonal to low-temperature l-T orthorhombic phase transition at $T_S \sim 170\text{K}$ [2]. Concomitant with the structural transition the Fe moments order in a commensurate AFM structure [3]. This compound becomes superconducting either under moderate applied pressure and or Na-doping [4,5]. The $\text{Ba}_{0.5}\text{K}_{0.5}\text{Fe}_2\text{As}_2$ and $\text{Sr}_{0.5}\text{Na}_{0.5}\text{Fe}_2\text{As}_2$ are superconductors with $T_c \sim 37\text{K}$ and $\sim 35\text{K}$, respectively. μSR measurements have shown a coexistence of superconductivity and phase separated static magnetic order in these compounds [6].

Mössbauer spectroscopy have been used to investigate the magnetic and structural phase transition of CaFe_2As_2 as well as the occurrence of phase separation in superconducting $\text{Ba}_{0.5}\text{K}_{0.5}\text{Fe}_2\text{As}_2$ and $\text{Sr}_{0.5}\text{Na}_{0.5}\text{Fe}_2\text{As}_2$ single crystals. A mosaic of single crystal plates, with the c axes parallel to γ -ray direction, were built to perform the Mössbauer transmission measurements. Room temperature measurements revealed that the main component of electric field gradient V_{zz} is along c axis for these ternary compounds. For the non superconducting CaFe_2As_2 an abrupt increase of the magnetic hyperfine field B_{hf} below $T_N \sim 170\text{K}$ was observed indicating a first-order magnetic transition. Low temperature spectra fits lead to $V_{zz} > 0$ with Fe moments lying in the (a,b) plane. The quadrupole splitting ΔE_Q values have a discontinuity at $\sim 170\text{K}$ confirming that structural and magnetic transition occurs concomitantly. The Mössbauer spectra of $\text{Ba}_{0.5}\text{K}_{0.5}\text{Fe}_2\text{As}_2$ and $\text{Sr}_{0.5}\text{Na}_{0.5}\text{Fe}_2\text{As}_2$ have a unique crystal site for Fe at room temperature, however at 4.2K the presence of two phases is clearly seen. For $\text{Ba}_{0.5}\text{K}_{0.5}\text{Fe}_2\text{As}_2$ $\sim 51\%$ of Fe is in a paramagnetic state while the remaining is in a magnetic phase with small magnetic moments ($\sim 0.15\mu_B$). For $\text{Sr}_{0.5}\text{Na}_{0.5}\text{Fe}_2\text{As}_2$ only $\sim 12\%$ of Fe are paramagnetic, the remaining Fe are in a magnetic state with magnetic moments of the order of $\sim 0.57\mu_B$.
